1	Introduction	13
1.1	Early Science and Mathematics	15
1.1.1	Lecture 1: (<i>Week 1</i>) Three Streams from the Pythagorean theorem	15
1.1.2	Pythagorean Triplets	16
1.1.3	What is mathematics?	17
1.1.4	Early Physics as Mathematics	17
1.1.5	The birth of modern mathematics	19
1.1.6	The Three Pythagorean Streams	20
1.2	Stream 1: Number Systems (9 Lectures)	21
1.2.1	Lecture 2: The Taxonomy of Numbers: $\mathbb{P}, \mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{I}, \mathbb{R}, \mathbb{C}$	22
1.2.2	Lecture 3: The role of physics in mathematics	26
1.2.3	Lecture 4: Prime numbers	30
1.2.4	Lecture 5: Early number theory: The Euclidean algorithm	33
1.2.5	Lecture 6: Early number theory: Continued fractions	34
1.2.6	Labor day: <i>Week 3</i>	37
1.2.7	Lecture 7: Pythagorean triplets (Euclid's formula)	37
1.2.8	Lecture 8: (<i>Week 3</i>) Pell's Equation	37
1.2.9	Lecture 9: (<i>Week 4</i>) Fibonacci sequence	40
1.2.10	Lecture 10: Exam I	41
1.3	Stream 2: Algebraic Equations (11 Lectures)	42
1.3.1	Lecture 11: (<i>Week 4</i>) Algebra and mathematics driven by physics	42
1.3.2	Lecture 12: (<i>Week 5</i>) Examples of nonlinear algebra in Physics	46
1.3.3	Lecture 13: Polynomial root classification (convolution)	47
1.3.4	Lecture 14: Introduction to Analytic Geometry	49
1.3.5	Lecture 15: (<i>Week 6</i>) Gaussian Elimination	52
1.3.6	Lecture 16: Transmission (ABCD) matrix composition method	53
1.3.7	Lecture 17: Riemann Sphere	54
1.3.8	Lecture 18: (<i>Week 7</i>) Complex analytic mappings (colorized plots)	56
1.3.9	Lecture 19: Signals: Fourier transforms	58
1.3.10	Lecture 20: Systems: Laplace transforms	59
1.3.11	Lecture 21: (<i>Week 8</i>) Network (System) Postulates	61
1.3.12	Lecture 22: Exam II	62
1.4	Stream 3a: Scalar Calculus (12 Lectures)	62
1.4.1	Lecture 23: (<i>Week 8</i>) Bernoulli to Euler	62
1.4.2	Lecture 24: (<i>Week 9</i>) Complex Analytic functions and the ROC	63
1.4.3	Lecture 25: Integration in the complex plane	64
1.4.4	Lecture 26: Cauchy-Riemann conditions	65
1.4.5	Lecture 27: (<i>Week 10</i>) Differential Calculus in the complex plane	66
1.4.6	Lecture 28: Three complex integration theorems	66
1.4.7	Lecture 29: Inverse Laplace transform (Cauchy residue theorem)	66
1.4.8	Lecture 30: (<i>Week 11</i>) Inverse Laplace transform and the Cauchy Residue Thm	66

1.4.9	Lecture 31: Case for causality: closing the contour	66
1.4.10	Lecture 32: Properties of the LT	66
1.4.11	Lecture 33: (<i>Week 12</i>) Multi-valued functions and Branch cuts	67
1.4.12	Lecture 34: The Riemann Zeta function $\zeta(s)$	67
1.4.13	Lecture 35: Exam III	67
1.5	Stream 3b: Vector Calculus (7 Lectures)	68
1.5.1	Lecture 36: Scalar Wave Equation	68
1.5.2	Lecture 37: (<i>Week 13</i>) Partial Diff Eqs of Physics;	68
1.5.3	Lecture 38: Vector dot and cross products	68
1.5.4	Thanksgiving Holiday 11/19–11/27 2016	68
1.5.5	Lectures 39: (<i>Week 14</i>) Vector operators	68
1.5.6	Lecture 40: Definitions of E, H, B, D; Maxwell's Equations	69
1.5.7	Lecture 41: Fundamental Theorem of Vector Calculus (Helmholtz theorem)	69
1.5.8	Lecture 42 (<i>Week 15</i>): Various topics	71
1.5.9	Lecture 43: Final overview	73
2	Number Systems: Stream 1	75
2.1	Week 2	75
2.1.1	Lec 4 Two theorems on primes	75
2.1.2	Lec 5 Greatest common divisor (GCD)	77
2.1.3	Lec 6 Continued Fraction Expansion (CFA)	79
2.2	Week 3	80

Abstract

An understanding of physics requires knowledge of mathematics. The contrary is not true. By definition, pure mathematics contains no physics. Yet historically, mathematics has a rich history filled with physical applications. Mathematics was developed by people with intent of making things work. In my view, as an engineer, I see these creators of early mathematics, as budding engineers. This book is an attempt to tell this story, of the development of mathematical physics, as viewed by an engineer.

The book is broken down into three topics, called streams, presented as five chapters: 1) Introduction, 2) Number systems, 3) Algebra Equations, 4) Scalar Calculus, and 5) Vector Calculus. The material is delivered as 40 “Lectures” spread out over a semester of 15 weeks, three lectures per week, with a 3 lecture time-out for administrative duties. Problems are provided for each week’s assignment. These problems are written out in L^AT_EX, with built in solutions, that may be expressed by un-commenting one line. Once the home-works are turned in, each student is given the solution. With regard to learning the material, the students rated these Assignments as the most important part of the course. There is a built in interplay between these assignments and the lectures. On many occasions I solved the homework in class, as motivation for coming to class. Four exams were given, one at the end of each of the three sections, and a final. Some of the exams were in class and some were evening exams, that ran over two hours. The final was two hours. Each of the exams, like the assignments, is provided as a L^AT_EX file, with solutions encoded with a one line software switch. The Exams are largely based on the Assignments. It is my philosophy that, in principle, the students could see the exam in advance of taking it.

Author’s Personal Statement

An expert is someone who has made all the mistakes in a small field. I don’t know if I would be called an expert, but I certainly have made my share of mistakes. I openly state that “I love making mistakes, because I learn so much from them.” One might call that the “expert’s corollary.”

This book has been written out of both my love for the topic of mathematical physics, and a frustration for wanting to share many key concepts, and even new ideas on these basic concepts. Over the years I have developed a certain *physical sense* of math, along with a related mathematical sense of physics. While doing my research,¹ I have come across what I feel are certain conceptual holes that need filling, and sense many deep relationships between math and physics, that remain unidentified. While what we presently teach is not wrong, it is missing these relationships. What is lacking is an intuition for how math “works.” We need to start listening to the language of mathematics. We need to let mathematics guide us toward our engineering goals.

It is my strong suspicion that over the centuries many others have had similar insights, and like me, have been unable to convey this slight misdirection. I hope these views can be useful to open young minds.

This marriage of math and physics will help us make progress in understanding the physical world. I turn to mathematics and physics when trying to understand the universe. I have arrived in my views following a lifelong attempt to understand human communication. This research arose from my 32 years at Bell Labs in the Acoustics Research Department. There such lifelong pursuits were not only possible, they were openly encouraged. The idea was that if you were successful at something, take it

¹<http://auditorymodels.org/index.php/Main/Publications>

as far as you can. But on the other side, don't do something well that's not worth doing. People got fired for the latter. I should have left for University after a mere 20 years,² but the job was just too cushy.

In this text it is my goal to clarify some of the conceptual errors when telling the story about physics and mathematics. My views have been often inspired by classic works, as documented in the bibliography. This book was inspired by my careful reading of Stillwell (2002), through Chapter 21 (Fig. 2). Somewhere in Chapter 22 I stopped reading and switched to the third edition (Stillwell, 2010), where I saw there was much more to master. At that point I saw that teaching this material to sophomores would allow me to absorb the more advanced material at a reasonable pace, which led to this book.

Back Cover Summary

This is foremost a math book, but not the typical math book. First, this book is for the engineering minded, for those who need to understand math to do engineering, to learn how things work. In that sense it is more about physics and engineering. Math skill are critical to making progress in building things, be it pyramids or computers, as clearly shown by the many great civilizations of the Chinese, Egyptians, Arabs (people of Mesopotamia), Greeks and Romans.

Second, this is a book about the math that developed to explain physics, to allow people to engineer complex things. To sail around the world one needs to know how to navigate. This requires a model of the planets and stars. You can only know where you are on earth if you understand where earth is, relative to the heavens. The answer to such a deep questions will depend on who you ask. The utility and accuracy of that answer depends critically on the depth of understanding of how the worlds and heavens work. Who is qualified to answer such question? It is best answered by those who study mathematics applied to the physical world.

Halley (1656–1742), the English astronomer, asked Newton (1643–1727) for the equation that describes the orbit of the planets. Halley was obviously interested in comets. Newton immediately answered “an ellipse.” It is said that Halley was stunned by the response (Stillwell, 2010, p. 176), as this was what had been experimentally observed by Kepler (c1619), and thus he knew Newton must have some deeper insight (Stillwell, 2010, p. 176).

When Halley asked Newton to explain how he knew this correct answer, Newton said he calculated it. But when challenged to show the calculation, Newton was unable to reproduce it. This open challenge eventually led to Newton's grand treatise, *Philosophiæ Naturalis Principia Mathematica* (July 5, 1687). It had a humble beginning, more as a letter to Halley, explaining how to calculate the orbits of the planets. To do this Newton needed mathematics, a tool he had mastered. It is widely accepted that Isaac Newton and Gottfried Leibniz invented calculus. But the early record shows that perhaps Bhāskara II (1114–1185 AD) had mastered this art well before Newton.³

Third, the main goal of this book is to teach engineering mathematics, in a way that it can be understood, remembered, and mastered, by anyone motivated to learn this topic. How can this near impossible goal be achieved? The answer is to fill in the gaps with “who did what, and when.” There is an historical story that may be told and mastered, by anyone serious about the science of making things.

One cannot be an expert in a field if they do not know the history of that field. This includes who the people were, what they did, and the credibility of their story. Do you believe the Pope or Galileo, on the topic of the relative position of the sun and the earth? The observables provided by science are clearly on Galileo's side. Who were those first engineers? They are names we all know: Archimedes, Pythagoras, Leonardo da Vinci, Galileo, Newton, All of these individuals had mastered mathematics. This book teaches the tools taught to every engineer. Do not memorize

²I should have left when AT&T Labs was formed, c1997. I started around December 1970, fresh out of Graduate school, and retired in December 2002.

³http://www-history.mcs.st-and.ac.uk/Projects/Pearce/Chapters/Ch8_5.html

complex formulas, rather make the equations “obvious” by teaching the simplicity of the underlying concept.

Credits

Besides thanking my parents, I would like to credit John Stillwell for his constructive, historical summary of mathematics. My close friend and colleague Steve Levinson somehow drew me into this project, without my even knowing it. My brilliant graduate student Sarah Robinson was constantly at my side, grading home-works and exams, and tutoring the students. Without her, I would not have survived the first semester the material was taught. Her proof-reading skills are amazing. Thank you Sarah for your infinite help. Finally I would like to thank John D’Angelo for putting up with my many silly questions. When it comes to the heavy hitting, John was always there to provide a brilliant explanation that I could easily translate into Engineer’ese (Matheering?) (i.e., Engineer language).

To write this book I had to master the language of mathematics (John’s language). I had already mastered the language of engineering, and a good part of physics.⁴ But we are all talking about the same thing. Via the physics and engineering, I already had a decent understanding of the mathematics, but I did not know that language. Hopefully, now I can get by.

Finally I would like to thank my wife (Sheau Feng Jeng aka Patricia Allen) for her unbelievable support and love. She delivered constant piece of mind, without which this project could never have been started, much less finish.

There are many others who played important roles, but they must remain anonymous, out of my fear of offending someone I forgot to mention.

–Jont Allen, Mahomet IL, Dec. 24, 2015

⁴Each genre (i.e, group) speaks their own dialect. One of my secondary goals is to bring down this scientific Tower of Bable.

Preface

It is widely acknowledged that interdisciplinary science is the backbone of modern scientific investigation. This is embodied in the STEM (Science, Technology, Engineering, and Mathematics) programs. Contemporary research is about connecting different areas of knowledge, thus it requires an understanding of cross-disciplines. However, while STEM is being taught, interdisciplinary science is not, due to its inherent complexity and breadth. Furthermore there are few people to teach it. Mathematics, Engineering and Physics (MEP) are at the core of such studies.⁵

STEM vs. MEP

Mathematics is based on the application rigor. Mathematicians specifically attend to the definitions of increasingly general concepts. Thus mathematics advances slowly, as these complex definitions must be collectively agreed upon. Mathematics shuns controversy, and embraces rigor, the opposite of uncertainty. Physics explores the fringes of uncertainty. Physicists love controversy. Engineering addresses the advancement the technology. Engineers, much like mathematicians, are uncomfortable with uncertainty, but are trained to deal with it.

To create such an interdisciplinary STEM program, a unified MEP curriculum is needed. In my view this unification could (should) take place based on a core mathematical training, from a historical perspective, starting with Euclid or before (i.e., Chinese mathematics), up to modern information theory and logic. As a bare minimum, the *fundamental theorems of mathematics* (arithmetic, algebra, calculus, vector calculus, etc.) need to be appreciated by every MEP student. The core of this curriculum is outlined in Table 1.1 (p. 21).

If, in the sophomore semester, students are taught a common MEP methodology and vocabulary, presented in terms of the history of mathematics, they will be equipped to

1. Exercise interdisciplinary science (STEM)
2. Communicate with other MEP trained (STEM) students and professors.

The goal is a *comprehensive understanding of the fundamental concepts of mathematics*, defined as those required for engineering. We assume that students with this deep understanding will end up being in the top 0.1% of Engineering. Time will tell if this assumption is correct.

The key tool is methodology. The traditional approach is a five to six course sequence: Calc I, II, III, DiffEq IV, Linear Algebra V and Complex Variables VI, over a time frame of three years (six semesters). This was the way I learned math. Following such a formal training regime, I felt I had not fully mastered the material, so I started over. I now consider myself to be self-taught. We need a more effective teaching method. I am not suggesting we replace the standard 6 semester math curriculum, rather I am suggesting replacing Calc I, II with this mathematical physics course, based on the historical thread, for those students who have demonstrated advanced ability. One needs more than a high school education to succeed in college engineering courses.

By teaching mathematics in the context of history, the student can fully appreciate the underlying principles. Including the mathematical history provides a uniform terminology for understanding the

⁵I prefer MEP over STEM, as being better focused on the people that do the work, organized around their scientific point of view.

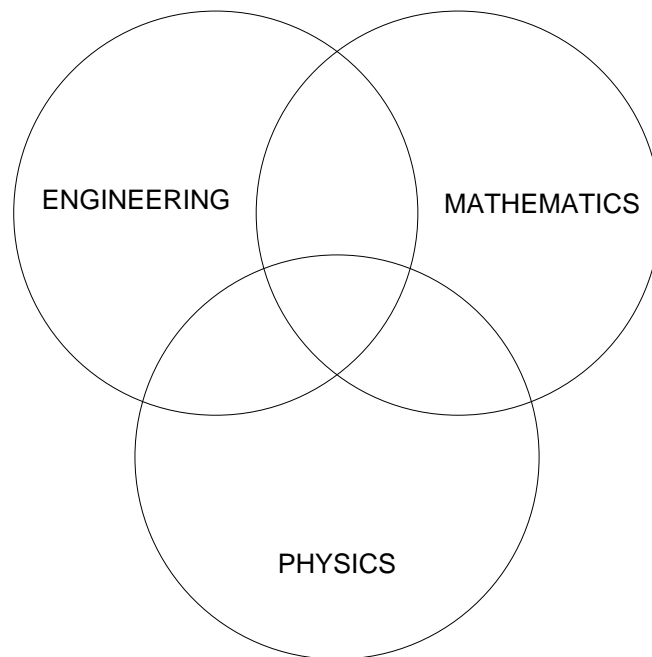

Figure 1: *There is a natural symbiotic relationship between Physics, Mathematics and Engineering, as depicted by this Venn diagram. Physics explores the boundaries. Mathematics provides the method and rigor. engineering transforms the method into technology. While these three disciplines work well together, there is poor communication due to a different vocabulary.*

fundamentals of mathematics. The present teaching method, using abstract proofs, with no (or few) figures or physical principles, by design removes intuition and the motivation that was available to the creators of these early theories. This present six semester approach does not function for many students, leaving them with a poor intuition.

1 Chapter 1

2 Introduction

3 Much of early mathematics centered around the love of art and music, due to our sensations of light
4 and sound. Exploring our physiological senses required a scientific understanding of vision and hearing,
5 as first explored by Newton (1687) and Helmholtz (1863a) (Stillwell, 2010, p. 261).¹ Our sense of color
6 and musical pitch are determined by the frequencies of light and sound. The Chinese and Pythagoreans
7 are well known for their early contributions to music theory. Pythagoras strongly believed that “all is
8 integer,” meaning that every number, and every mathematical and physical concept, could be explained
9 by integral relationships. It is likely that this belief was based on Chinese mathematics from thousands
10 of years earlier. It is also known that his ideas about the importance of integers were based on what
11 was known about music theory in those days. For example it was known that the relationships between
12 the musical notes (pitches) obey natural integral relationships.

13 Other important modern applications of number theory are present with

- 14 • Public-private key encryption: which requires the computationally intensive factoring of large
15 integers
- 16 • IEEE Floating point²

17 As acknowledged by Stillwell (2010, p. 16), the Pythagorean view is relevant today

18 *With the digital computer, digital audio, and digital video coding everything, at least*
19 *approximately into sequences of whole numbers, we are closer than ever to a world in which*
20 *“all is number.”*

21 Mersenne (1588-1647) contributed to our understanding of the relationship between the wavelength
22 and the length of musical instruments. These results were extended by Galileo’s father, and then by
23 Galileo himself (1564-1642). Many of these musical contributions resulted in new mathematics, such as
24 the discovery of the wave equation by Newton (c1687), followed by its one-dimensional general solution
25 by d’Alembert (c1747).

26 By that time there was a basic understanding that sound and light traveled at very different speeds
27 (thus why not the velocities of different falling weights?).

28 Ole Rømer first demonstrated in 1676 that light travels at a finite speed (as opposed to
29 instantaneously) by studying the apparent motion of Jupiter’s moon Io. In 1865, James
30 Clerk Maxwell proposed that light was an electromagnetic wave, and therefore traveled at
31 the speed c appearing in his theory of electromagnetism.³

32 Galileo famously conceptualized an experiment in 1589 where he suggested dropping two different
33 weights from the Leaning Tower of Pisa, and showed that they must take the same time to hit the

¹<https://en.wikipedia.org/wiki/Acoustics>

²https://en.wikipedia.org/wiki/IEEE_floating_point\#Formats

³https://en.wikipedia.org/wiki/Speed_of_light

34 ground. Conceptually this is an important experiment, driven by a mathematical argument in which
 35 he considered the two weights to be connected by an elastic cord. This resulted in the concept of
 36 conservation of energy, one of the cornerstones of modern physical theory.

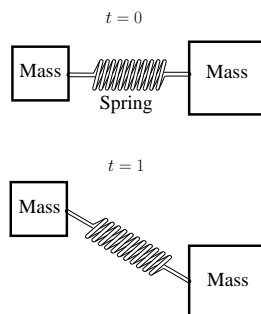

Figure 1.1: Depiction of the argument of Galileo (unpublished book of 1638) as to why weights of different masses (weight) must fall with identical velocity. By joining them with an elastic cord they become one. Thus if the velocity were proportional to the mass, the joined masses would fall even faster. This results in a logical fallacy. This may have been the first time that the principle of conservation of energy was clearly stated.

37 While Newton may be best known for his studies on light, he was the first to predict the speed of
 38 sound. However his theory was in error by⁴ $\sqrt{c_p/c_v} = \sqrt{1.4} = 1.183$. This famous error would not be
 39 resolved for over two hundred years, awaiting the formulation of thermodynamics by Laplace, Maxwell
 40 and Boltzmann, and others. What was needed was the concept of constant-heat, or *adiabatic process*.
 41 For audio frequencies (0.02-20 [kHz]), the small temperature gradients cannot diffuse the distance of a
 42 wavelength in one cycle (Pierce, 1981; Boyer and Merzbach, 2011), “trapping” the heat energy in the
 43 wave. There were several other physical enigmas, such as the observation that sound disappears in a
 44 vacuum and that a vacuum cannot draw water up a column by more than 34 feet.

45 There are other outstanding examples where physiology impacted mathematics. Leonardo da Vinci
 46 is well known for his studies of the human body. Helmholtz’s theories of music and the percep-
 47 tion of sound are excellent examples of under-appreciated fundamental mathematical contributions
 48 (Helmholtz, 1863a). Lord Kelvin (aka William Thompson),⁵ was one of the first true engineer-scientists,
 49 equally acknowledged as a mathematical physicist and well known for his interdisciplinary research,
 50 knighted by Queen Victoria in 1866. Lord Kelvin coined the term *thermodynamics*, a science more
 51 fully developed by Maxwell (the same Maxwell of electrodynamics). Thus the interdisciplinary nature
 52 of science has played many key roles in the development of thermodynamics.⁶ Lord Rayleigh’s book on
 53 the theory of sound (Rayleigh, 1896) is a classic text, read even today by anyone who studies acoustics.
 54

55 It seems that we have detracted from this venerable interdisciplinary view of science by splitting the
 56 disciplines into into smaller parts whenever we perceived a natural educational boundary. Reforging
 57 these natural connections at some point in the curriculum is essential for the proper training of students,
 58 both scientists and engineers.⁷

59 WEEK 1

60

⁴The square root of the ratio of the specific heat capacity at constant pressure to that at constant volume

⁵Lord Kelvin was one of half a dozen interdisciplinary mathematical physicists, all working about the same time, that made a fundamental change in our scientific understanding. Others include Helmholtz, Stokes, Green, Heaviside, Rayleigh and Maxwell.

⁶Thermodynamics is another example of a course that needs reworking along historical lines.

⁷Perhaps its time to put the MEP Humpty Dumpty back together.

61 1.1 Early Science and Mathematics

62 The first 5,000 years is not well document, but the basic record is clear, as outlined in Fig. 1.2. Thanks
 63 to Euclid and later Diophantus (c250 CE), we have some limited understanding of what they studied.
 64 For example, Euclid's formula (Fig. 2.3, Eq. 2.3) provides a method for computing all Pythagorean
 65 triplets (Stillwell, 2010, pp. 4-9).

66 Chinese Bells and stringed musical instruments were exquisitely developed in their tonal quality, as
 67 documented by ancient physical artifacts (Fletcher and Rossing, 2008). In fact this development was
 68 so rich that one must question why the Chinese failed to initiate the industrial revolution. Specifically,
 69 why did Europe eventually dominate with its innovation when it was the Chinese who did the extensive
 70 early invention?

71 According to Lin (1995) this is known as the *Needham question*:

72 “Why did modern science, the mathematization of hypotheses about Nature, with all its
 73 implications for advanced technology, take its meteoric rise only in the West at the time of
 74 Galileo[, but] had not developed in Chinese civilization or Indian civilization?”

75 Needham cites the many developments in China:⁸

76 “Gunpowder, the magnetic compass, and paper and printing, which Francis Bacon consid-
 77 ered as the three most important inventions facilitating the West's transformation from the
 78 Dark Ages to the modern world, were invented in China.” (Lin, 1995)

79 “Needham's works attribute significant weight to the impact of Confucianism and Taoism on
 80 the pace of Chinese scientific discovery, and emphasizes what it describes as the ‘diffusionist’
 81 approach of Chinese science as opposed to a perceived independent inventiveness in the
 82 western world. Needham held that the notion that the Chinese script had inhibited scientific
 83 thought was ‘grossly overrated’ ” (Grosswiler, 2004).

84 Lin was focused on military applications, missing the importance of non-military applications. A
 85 large fraction of mathematics was developed to better understand the solar system, acoustics, musical
 86 instruments and the theory of sound and light. Eventually the universe became a popular topic, and
 87 still is today.

88 1.1.1 Lec 1 The Pythagorean theorem

While early Asian mathematics is not fully documented, it clearly defined the course for at least several
 thousand years. The first recorded mathematics was that of the Chinese (5000-1200 BCE) and the
 Egyptians (3,300 BEC). Some of the best early record were left by the people of Mesopotamia (Iraq,
 1800 BEC). Thanks to Euclid's Elements (c323 BEC) we have an historical record, tracing the progress
 in geometry, as defined by the Pythagorean theorem *for any right triangle*

$$c^2 = a^2 + b^2, \quad (1.1)$$

89 having sides of lengths (a, b, c) that are positive real numbers with $c > [a, b]$ and $a + b > c$. Solutions
 90 were likely found by trial and error rather than by an algorithm.

If a, b, c are lengths, then a^2, b^2, c^2 are areas. Equation 1.1 says that the area a^2 of a square plus
 the area b^2 of a square equals the area c^2 of square. Today a simple way to prove this is to compute
 the magnitude of the complex number $c = a + bj$, which forces the right angle

$$|c|^2 = (a + bj)(a - bj) = a^2 + b^2.$$

⁸https://en.wikipedia.org/wiki/Joseph_Needham#cite_note-11

91 However, complex arithmetic was not an option for the Greek mathematicians, since complex numbers
92 and algebra had yet to be invented.

93 **Almost 700 years after** Euclid's *Elements*, the Library of Alexandria was destroyed (391 EC) by
94 fire, taking with it much of the accumulated Greek knowledge. Thus one of the best technical records
95 may be Euclid's *Elements*, along with some sparse mathematics due to Archimedes (c300 BEC) on
96 geometrical series, computing the volume of a sphere, and the area of the parabola, and elementary
97 hydrostatics. Additionally, a copy of a book by Diophantus *Arithmetic* was discovered by Bombelli
98 (c1572) in the Vatican library (Stillwell, 2010, p. 51).

Chronological history pre 16th century

1.1.2a

200th BCE Chinese (Primes; quadratic equation; Euclidean algorithm (GCD))

180th BCE Babylonia (Mesopotamia/Iraq) (quadratic equation)

6th BCE Pythagoras (Thales) and the Pythagorean "tribe"

4th BCE Archimedes 300BCE; Euclid (quadratic equation)

3rd CE Diophantus c250CE;

4th CE Alexandria Library destroyed 391CE;

7th CE Brahmagupta (negative numbers; quadratic equation)

9th CE al-Khwārizmī (algebra) 830CE

10th CE Bhaskara (calculus) 1114-1183

15th Leonardo & Copernicus 1473-1543

16th Tartaglia (cubic eqs); Bombelli 1526-1572; Galileo Galilei 1564-1642

Time Line

Figure 1.2: Mathematical time-line between 1500 BCE and 1650 CE.

99 1.1.2 Pythagorean Triplets

100 Well before Pythagoras, the Babylonians had tables of *Pythagorean triplets* (PTs), integers $[a, b, c]$
101 that obey Eq. 1.1. An example is $[3, 4, 5]$. A stone tablet (Plimpton-322) dating back to 1800 [BCE]
102 (Fig. 1.9) was found with integers for $[a, c]$. Given such sets of two numbers, which determined a third
103 positive integer b such that $b = \sqrt{c^2 - a^2}$, this table is more than convincing that the Babylonians were
104 well aware of PTs, but less convincing that they had access to Euclid's formula (Eq. 1.3).

105 It seems likely that Euclid's *Elements* was largely the source of the fruitful 6th century era due to
106 the Greek Mathematician Diophantus (Fig. 1.2), who developed the concept of *discrete mathematics*,
107 now known as *Diophantine analysis*.

108 The work of Diophantus was followed by a rich mathematical era, with the discovery of 1) early cal-
109 culus (Brahmagupta, 7th CE), 2) algebra (al-Khwārizmī, 9th CE), and 3) complex arithmetic (Bombelli,
110 15th CE). This period overlapped with the European middle (i.e., dark) ages. Presumably European in-
111 tellectuals did not stop thinking during these many centuries, but what happened in Europe is presently
112 unclear given the available records.⁹

⁹It might be interesting to search the archives of the monasteries, where the records were kept, to figure out what

1.1.3 What is mathematics?

Mathematics is a language, not so different from other languages. Today's mathematics is a written language with an emphasis on symbols and glyphs, biased toward Greek letters. The etymology of these symbols would be interesting to study. Each symbol is dynamically assigned a meaning, appropriate for the problem being described. These symbols are then assembled to make sentences. It is similar to Chinese in that the spoken and written version are different across dialects. In fact, like Chinese, the sentences may be read out loud in the language (dialect) of your choice, while the mathematical sentence (like Chinese) is universal.

Math is a language: It seems strange when people complain that they “can't learn math,”¹⁰ but they claim to be good at languages. Math is a language, with the symbols taken from various languages, with a bias toward Greek, due to the popularity of Euclid's Elements. Learning a new language is fun because it opens doors to other cultures.

Math is different due to the rigor of the rules of the language, along with the way it is taught (e.g., not as a language). A third difference between math and the romance languages is that math evolved from physics, with important technical applications. This was the concept behind the Pythagorean school, a band of followers called the *Pythagoreans*. Learning languages is an advanced social skill. Thus the social outcomes are very different between learning a romance language and math. A further problem is that pre-high-school, students confuse arithmetic with math. The two topics are very different, and students need to understand this. One does not need to be good at arithmetic to be good at math (but it doesn't hurt).

There are many rules that must be mastered. These rules are defined by algebra. For example the sentence $a = b$ means that the number a has the same value as the number b . The sentence is spoken as “a equals b.” The numbers are nouns and the equal sign says they are equivalent, playing the role of a verb, or action symbol. Following the rules of algebra, this sentence may be rewritten as $a - b = 0$. Here the symbols for minus and equal indicate two types of actions.

Sentences can become arbitrarily complex, such as the definition of the integral of a function, or a differential equation. But in each case, the mathematical sentence is written down, may be read out loud, has a well defined meaning, and may be manipulated into equivalent forms following the rules of algebra and calculus. This language of mathematics is powerful, with deep consequences, known as proofs.

The writer of an equation should always translate (explicitly summarize the meaning of the expression), so the reader will not miss the main point. This is simply a matter of clear writing.

Language may be thought of as mathematics (turning this idea on its head). To properly write correct English it is necessary to understand the construction of the sentence. It is important to identify the subject, verb, object, and various types of modifying phrases. If you wish to read about this, look up the distinction between the words *that* and *which*, which make a nice example of this concept. Most of us work directly with what we think “sounds right,” but if you're learning English as a second language, it is very helpful to understand these mathematical rules, which are arguably easier to master than the foreign phones (i.e., speech sounds).

1.1.4 Early Physics as Mathematics

Mathematics has many functions, but basically it summarizes an algorithm (a set of rules). It was clear to Pythagoras (and many others before him), that there was an important relationship between mathematics and the physical world. Pythagoras may have been one of the first to capitalize on this relationship, using science and mathematics to design and make things.¹¹ This was the beginnings of technology as we know it, coming from the relationship between physics and math, impacting

happened during this strange time.

¹⁰“It looks like Greek to me.”

¹¹It is likely that the Chinese and Egyptians also did this, but this is more difficult to document.

Figure 13.10: Portrait of Jakob Bernoulli by Nicholas Bernoulli

Figure 13.11: Johann Bernoulli

Figure 10.4: Leonhard Euler

Figure 1.3: Above: Jakob (1655-1705) and Johann (1667-1748) Bernoulli; Below: Leonhard Euler (1707) and Jean le Rond d'Alembert (1717-1783). The figure numbers are from Stillwell (2010).

158 map making, tools, implements of war (the wheel, gunpowder), art (music), sound, water transport,
 159 sanitation, secure communication, food, . . . , etc.

160 Why is Eq. 1.1 called a *theorem*, and what exactly needs to be proved? We do not need to prove
 161 that (a, b, c) obey this relationship, since this is a condition that is observed. We do not need to prove
 162 that a^2 is the area of a square, as this is the definition of the area of a square. What needs to be proved
 163 is that this relation only holds if the angle between the two shorter sides is 90° .

164 To appreciate the significance of this development it is helpful to trace the record back to before
 165 the time of the Greeks. The Pythagorean theorem (Eq. 1.1) did not begin with Euclid or Pythagoras.
 166 Rather Euclid and Pythagoras appreciated the importance of these ideas and documented them.

167 In the end the Pythagoreans were destroyed by fear. This may be the danger of mixing technology
 168 and politics:

169 “Whether the complete rule of number (integers) is wise remains to be seen. It is said that
 170 when the Pythagoreans tried to extend their influence into politics they met with popular
 171 resistance. Pythagoras fled, but he was murdered in nearby Mesopotamia in 497 BCE.”

172 –Stillwell (2010, p. 16)

173 1.1.5 The birth of modern mathematics

174 Modern mathematics (what we know today) was born in the 15-16th century, in the hands of Leonardo
 175 da Vinci, Bombelli, Galileo, Descartes, Fermat, and many others (Stillwell, 2010). Many of these early
 176 master were, like the Pythagoreans, secretive to the extreme about how they solved problems. They
 177 had no interest in sharing their ideas. This soon changed by Mersenne, Descartes and Newton, causing
 178 mathematics to blossom.

179 **The amazing Bernoulli family** The first individual that seems to have openly recognized the
 180 importance of mathematics, to actually teach it, was Jacob Bernoulli (Fig. 1.3). Jacob worked on what
 181 is now view as the standard package of analytic “circular” (i.e., periodic) functions: $\sin(x)$, $\cos(x)$,
 182 $\exp(x)$, $\log(x)$.¹² Eventually the full details were developed (for real variables) by Euler (Section 1.3.8
 183 and 3.4.1).

184 From Fig. 1.4 we see that he was contemporary to Galileo, Mersenne, Descartes, Fermat, Huygens,
 185 Newton, and Euler. Thus it seems likely that he was strongly influenced by Newton, who in turn was
 186 influenced by Descartes,¹³ Viète and Wallis (Stillwell, 2010, p. 175). With the closure of Cambridge
 187 University due to the plague of 1665, Newton returned home, Woolsthorpe-by-Colsterworth (95 [mi]
 188 north of London), to worked by himself, for over a year.

189 Jacob Bernoulli, like all successful mathematicians of the day, was largely self taught. Yet Jacob
 190 was in a new category of mathematicians, because he was an effective teacher. Jacob taught his sibling
 191 Johann, who then taught his sibling Daniel. But most importantly, Johann taught Leonhard Euler
 192 (Figs. 1.4, 1.3), the most prolific (thus influential) of all mathematicians. This resulted in an explosion
 193 of new ideas and understanding. It is most significant that all four mathematicians published their
 194 methods and findings. Much later, Jacob studied with students of Descartes¹⁴ (Stillwell, 2010, p. 268-9).

195 Euler went far beyond all the Bernoulli family, Jacob, Johann and Daniel, (Stillwell, 2010, p. 315).
 196 A special strength of Euler was the degree to which he published. First he would master a topic, and
 197 then he would publish. His papers continued to appear long after his death (Calinger, 2015).

198 Another individual of that time of special note, who also published extensively, was d’Alembert
 199 (Figs. 1.4, 1.3). Some of the most important tools were first proposed by d’Alembert. Unfortunately,
 200 and perhaps somewhat unfairly, his rigor was criticized by Euler, and later by Gauss (Stillwell, 2010).

¹²The log and tan functions are related by $\tan^{-1}(z) = -\frac{1}{2} \ln\left(\frac{1-z}{1+z}\right)$.

¹³https://en.wikipedia.org/wiki/Early_life_of_Isaac_Newton

¹⁴It seems clear that Descartes was also a teacher.

201 Once the tools were being openly published, mathematics grew exponentially. It was one of the
 202 most creative times in mathematics. Figure 1.4 shows the list of the many famous names, and their
 203 relative time-line. To aid in understand the time line, note that Leonhard Euler was a contemporary
 204 of Benjamin Franklin, James Clerk Maxwell of Abraham Lincoln.¹⁵

Chronological history post 16th century 1.1.2b

205 1.1.6 Three Streams from the Pythagorean theorem

206 From the outset of his presentation, Stillwell (2010, p. 1) defines “three great *streams* of mathematical
 207 thought: *Numbers, Geometry and Infinity*,” that flow from the Pythagorean theorem, as summarized
 208 in Table 1.1. Namely the Pythagorean theorem is the spring from which flow the three streams of
 209 *all* mathematics. This is a useful concept, based on reasoning not as obvious as one might think.
 210 Many factors are in play here. One of these was the strongly held opinion of Pythagoras that all
 211 mathematics should be based on integers. The rest are tied up in the long, necessarily complex history
 212 of mathematics, as best summarized by the Fundamental theorems, which are each discussed in detail
 213 in the appropriate chapter.

214 Stillwell’s concept of three streams following from the Pythagorean theorem is the organizing prin-
 215 ciple behind the this book, organized by chapter:

- 216 1. *Introduction* (Chapter 1) A detailed overview of the fundamentals and the three streams are
 217 presented in Sections 1.2–1.5.
- 218 2. *Number Systems* (Chapter 2: Stream 1) Fundamentals of number systems, starting with prime
 219 numbers, through complex numbers, vectors and matrices.
- 220 3. *Algebraic Equations* (Chapter 3: Stream 2) Algebra and its development, as we know it today.
 221 The theory of real and complex equations and functions of real and complex variables. Complex
 222 impedance $Z(s)$ of complex frequency $s = \sigma + \omega j$ is covered with some care, given its importance
 223 for engineering mathematics.

¹⁵Lincoln traveled through Mahomet IL (where I live) on his way to the Urbana Court house.

- 224 4. *Scalar Calculus* (Chapter 4: Stream 3a) Ordinary differential equations. Integral theorems.
 225 Acoustics.
- 226 5. *Vector Calculus*: (Chapter 5: Stream 3b) Vector Partial differential equations. Gradient, diver-
 227 gence and curl differential operators. Stokes, and Green's theorems. Maxwell's equations.

Table 1.1: *Three streams followed from Pythagorean theorem: Number Systems (Stream 1), Geometry (Stream 2) and Infinity (Stream 3).*

-
- *The Pythagorean Theorem is the mathematical spring which bore the three streams.*
 - *≈Several centuries per stream:*
 - 1) **Numbers:**
 - 6th BC* \mathbb{N} counting numbers, \mathbb{Q} (Rationals), \mathbb{P} Primes
 - 5th BC* \mathbb{Z} Common Integers, \mathbb{I} Irrationals
 - 7th CE* zero $\in \mathbb{Z}$
 - 2) **Geometry:** (e.g., lines, circles, spheres, toroids, ...)
 - 17th CE* Composition of polynomials (Descartes, Fermat)
Euclid's Geometry + algebra \Rightarrow Analytic Geometry
 - 18th CE* Fundamental Theorem of Algebra
 - 3) **Infinity:** ($\infty \rightarrow$ Sets)
 - 17-18th CE* \mathbb{F} Taylor series, Functions, Calculus (Newton)
 - 19th CE* \mathbb{R} Real, \mathbb{C} Complex 1851
 - 20th CE* Set theory
-

228 1.2 Stream 1: Number Systems

229 This era produced a new stream of fundamental theorems. A few of the individuals who played a
 230 notable role in this development, in chronological (birth) order, include Galileo, Mersenne, Newton,
 231 d'Alembert, Fermat, Huygens, Descartes and Helmholtz. These individuals were some of the first
 232 to develop the basic ideas, in various forms, that were then later reworked into the proofs, that today
 233 we acknowledge as *The fundamental theorems of mathematics*.

234 Number theory (discrete, i.e., integer mathematics) was a starting point for many key ideas. For
 235 example, in Euclid's geometrical constructions the Pythagorean theorem for $\{a, b, c\} \in \mathbb{R}$ was accepted
 236 as true, but the emphasis in the early analysis was on integer constructions, such as Euclid's formula
 237 for Pythagorean triplets (Eq. 1.3, Fig. 2.3) k As we shall see, the Pythagorean theorem is a rich source
 238 of mathematical constructions, such as composition of polynomials, and solutions of Pell's equation by
 239 eigenvector and recursive analysis methods. Recursive difference equation solutions predate calculus, at
 240 least going back to the Chinese (c2000 BCE). These are early (pre-limit) forms of differential equations,
 241 best analyzed using an eigenfunction expansion (Appendix D), a powerful geometrical concept from
 242 linear algebra, of an expansion in terms of an orthogonal set of normalized (unit-length) vectors.

243 **The first use of zero and ∞ :** It is hard to imagine that one would not appreciate the concept of
 244 zero and negative numbers when using an abacus. If five beads are moved up, and one is moved down,
 245 then four are left. Then if four more are move down, that leaves zero. Taking away is the opposite
 246 of addition, and taking away from four to get zero beads, is no different than taking four away from
 247 zero, to get negative four beads. Subtraction, the inverse of addition, seems like an obvious idea, on
 248 an abacus.

249 However, understanding the concept of zero and negative numbers is not the same as having a
 250 symbolic notation. The Roman number system had no such symbols. The first recorded use of a
 251 symbol for zero is said to be by Brahmagupta in 628 CE.¹⁶ Thus it does not take much imagination
 252 to go from counting numbers \mathbb{N} to the set of all integers \mathbb{Z} , including zero, but apparently it takes 600
 253 years to develop a terminology that represents these ideas. Defining the rules of subtraction required
 254 the creation of algebra c830 CE (Fig. 1.2). The concept that caused far more difficulty was ∞ . Until
 255 Riemann's thesis in 1851 it was not clear if ∞ was a number, many numbers, or even definable.

256 1.2.1 Lec 2: The Taxonomy of Numbers: $\mathbb{P}, \mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{I}, \mathbb{R}, \mathbb{C}$

257 Once symbols for zero and negative numbers were defined (and accepted), progress was made. In
 258 a similar manner, to fully understand numbers, a transparent notation is required. First one must
 259 differentiate between the different classes (genus) of numbers, providing a notation that defines each of
 260 these classes, along with their relationships. It is logical to start with the most basic *counting numbers*,
 261 which we indicate with the double-bold symbol \mathbb{N} . All the double-bold symbols and their genus are
 262 summarized in Appendix A.

263 **Counting numbers \mathbb{N} :** These are known as the “natural numbers” $\{1, 2, 3, \dots\} \in \mathbb{N}$, denoted by
 264 the double-bold symbol \mathbb{N} . For increased clarity we shall refer to the natural numbers as *counting*
 265 *numbers*, to clarify that *natural* means *integer*. The mathematical sentence $2 \in \mathbb{N}$ is read as *2 is a*
 266 *member of the set of counting numbers*. The word *set* means the *sharing of a specific property*.

267 **Primes \mathbb{P} :** A prime number $\mathbb{P} \subset \mathbb{N}$ (set \mathbb{P} is a subset of \mathbb{N}) is an integer that may not be factored,
 268 other than by 1 and itself. Since $1 = 1 \cdot 1$, $1 \notin \mathbb{P}$, as it is seen to violate this basic definition of a prime.
 269 Prime numbers \mathbb{P} are a *subset* of the counting numbers ($\mathbb{P} \subset \mathbb{N}$). We shall use the convenient notation
 270 π_n for the prime numbers, indexed by $n \in \mathbb{N}$. The first 12 primes ($n = 1, \dots, 12$) are $\pi_n = 2, 3, 5, 7, 11,$
 271 $13, 17, 19, 23, 29, 31, 37$. Since, $4 = 2^2$ and $6 = 2 \cdot 3$ may be factored, $\{4, 6\} \notin \mathbb{P}$ (read as: *4 and 6 are*
 272 *not in the set of primes*). Given this definition, multiples of a prime, i.e., $n\pi_k \equiv [2, 3, 4, 5, \dots \text{times} \pi_k$
 273 *of any prime π_k , cannot be prime. It follows that all primes except 2 must be odd and every integer*
 274 *N is unique in its factorization.*

275 *Coprimes* are number whose factors are distinct (they have no common factors). Thus 4 and 6 are
 276 not coprime, since they have a common factor of 2, whereas $21 = 3 \cdot 7$ and $10 = 2 \cdot 5$ are coprime. By
 277 definition all distinct primes are coprime. The notation $m \perp n$ indicates that m, n are coprime.

278 The *Fundamental Theorem of Arithmetic* states that all integers may be uniquely expressed as a
 279 product of primes. The *Prime Number Theorem* estimates the mean density of primes over \mathbb{N} .

280 **Integers \mathbb{Z} :** These include positive and negative counting numbers and zero. Notionally we might
 281 indicate this using *set notation* as $\mathbb{Z} : \{-\mathbb{N}, 0, \mathbb{N}\}$. Read this as *The integers are in the set composed of*
 282 *the negative of the natural numbers ($-\mathbb{N}$), zero, and counting numbers \mathbb{N} . Note that $\mathbb{N} \subset \mathbb{Z}$.*

283 **Rational numbers \mathbb{Q} :** These are defined as numbers formed from the ratio of two integers. Since
 284 the integers \mathbb{Z} include 1, it follows that integers are a subset of rational numbers ($\mathbb{Z} \subset \mathbb{Q}$). For example
 285 the rational number $3/1 \in \mathbb{Z}$. The main utility of rational numbers is that that they can efficiently
 286 approximate any number on the real line, to any precision. For example $\pi \approx 22/7$ with a relative error
 287 of $\approx 0.04\%$. Of course, if the number is rational the error is zero.

288 **Fractional number \mathbb{F} :** The utility of rational numbers is their power to approximate irrational
 289 numbers ($\mathbb{R} \not\subset \mathbb{Z}$). It follows that a subset of the rationals, that excludes the integers, has great value.
 290 We call these numbers *Fractional numbers* and assign them the symbol \mathbb{F} . They are defined as the
 291 subset of rationals that are not integers. From this definition $\mathbb{F} \perp \mathbb{Z}$, $\mathbb{F} \subset \mathbb{Q} = \mathbb{Z} \cup \mathbb{F}$. Because of their

¹⁶The fall of the Roman Empire was Sept. 4, 476.

approximating property, the fractional set \mathbb{F} represent the most important (and the largest) portion of the rational numbers, dwarfing the size of the integers, another good reason for defining the two distinct subsets.

Once factored and common factors canceled, the subset $\mathbb{F} \subset \mathbb{Q}$ of rational numbers is always the ratio of coprimes. For example $\pi \approx 22/7 = 11 \cdot 2/7 = 3 + 1/7$ with $22 \perp 7$, and $9/6 = 3/2 = 1 + 1/2$ with $3 \perp 2$.¹⁷

Irrational numbers \mathbb{I} : Every real number that is not rational (\mathbb{Q}) is *irrational* ($\mathbb{Q} \perp \mathbb{I}$). Irrational numbers include π, e and the square roots of most integers (i.e., $\sqrt{2}$). These are decimal numbers that never repeat, thus requiring infinite precision in their representation.

Irrational numbers (\mathbb{I}) were famously problematic for the Pythagoreans, who incorrectly theorized that all numbers were rational. Like ∞ , irrational numbers require a new and difficult concept before they may even be defined: They were not in the set of fractional numbers ($\mathbb{I} \not\subset \mathbb{F}$). It was easily shown, from a simple geometrical construction, that most, but not all of the square roots of integers are irrational. It was essential to understand the factorization of counting numbers before the concept of irrationals could be sorted out.

Real numbers \mathbb{R} : Reals are the union of rational and irrational numbers, namely $\mathbb{R} : \{\mathbb{I}, \mathbb{Q}\}$ ($\mathbb{R} = \mathbb{Z} \cup \mathbb{F} \cup \mathbb{I}$). Reals are the lengths in Euclidean geometry. Many people assume that *IEEE 754 floating point numbers* (c1985) are real (i.e., $\in \mathbb{R}$). In fact they are rational ($\mathbb{Q} : \{\mathbb{F} \cup \mathbb{Z}\}$) approximations to real numbers, designed to have a very large dynamic range. There can be no machine realization of irrational numbers, since such a number would require infinite precision (∞ bits). The hallmark of fractional numbers (\mathbb{F}) is their power in making highly accurate approximations of any real number.

Using Euclid's compass and ruler methods, one can make line length proportionally shorter or longer, or (approximately) the same. A line may be made be twice as long, an angle bisected. However, the concept of an integer length in Euclid's geometry was not defined.¹⁸ Nor can one construct an imaginary or complex line as all lines are assumed to be real.

Real numbers were first fully accepted only after set theory was developed by Cantor (1874) (Stillwell, 2010, pp. 461, 525. . .). It seems amazing, given how widely accepted real numbers are today. But in some sense they were accepted by the Greeks, as lengths of real lines.

Complex numbers \mathbb{C} : Complex numbers are best defined as *ordered pairs of real numbers*.¹⁹ They are quite special in engineering mathematics, since roots of polynomials having either real or complex coefficients may be complex. The best known example is the quadratic formula for the roots of a 2^d degree polynomial, with either real or complex coefficients.

The common way to write a complex number is using the common notation $z = a + bj \in \mathbb{C}$, where $a, b \in \mathbb{R}$. Here $1j = \sqrt{-1}$. We also define $1i = -1j$ to account for the two possible signs of the square root. Accordingly $1j^2 = 1i^2 = -1$.

Multiplication of complex numbers follows the rules of real algebra, similar to multiplying two polynomials. Multiplication of two first degree polynomials gives

$$(a + bx)(c + dx) = ac + (ad + bc)x + bdx^2$$

If we substitute $1j$ for x , and use the definition $1j^2 = -1$, we obtain the product of the two complex numbers

$$(a + bj)(c + dj) = ac - bd + (ad + bc)j.$$

¹⁷HW problem: How to define \mathbb{F} given two integers $(n, m) \subset \mathbb{Z}$? Sol: Not sure how to approach this, but it seems like a fun problem. Here two simple methods that do *not* work: (1) One cannot define \mathbb{F} as the ratio $x = n/m$, since given $m = 1, x \in \mathbb{Z}$. (2) One cannot define \mathbb{F} as the ratio of two coprimes, since then $x = 1/m \notin \mathbb{F}$ (since $1 \perp \mathbb{P}$).

¹⁸As best I know.

¹⁹A polynomial $a + bx$ and a 2-vector $[a, b]^T = \begin{bmatrix} a \\ b \end{bmatrix}$ are also examples of ordered pairs.

327 Thus multiplication of complex numbers obeys the accepted rules of algebra.

Polar representation: An alternative for complex multiplication is to work with polar coordinates. The polar form of complex number $z = a + bj$ is written in terms of its magnitude $\rho = \sqrt{a^2 + b^2}$ and angle $\theta = \angle z = \tan^{-1}(z) = \arctan z$, as $z = \rho e^{\theta j}$. From the definition of the complex natural log function

$$\ln \rho e^{\theta j} = \ln \rho + \theta j,$$

328 which is useful in engineering calculations.²⁰

Matrix representation: A second alternative and useful way to represent complex numbers is in terms of 2x2 matrices. This relationship is defined by the mapping from a complex number to a 2x2 matrix

$$a + jb \leftrightarrow \begin{bmatrix} a & -b \\ b & a \end{bmatrix}.$$

You might verify that

$$\frac{a + bj}{c + dj} = \frac{ab + bd + (bc - ad)j}{c^2 + d^2} \leftrightarrow \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{bmatrix} c & -d \\ d & c \end{bmatrix}^{-1} = \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{bmatrix} c & d \\ -d & c \end{bmatrix} \frac{1}{c^2 + d^2}.$$

329 By taking the inverse of the 2x2 matrix one can define the ratio of one complex number by another,
330 Until you try out this representation, it may not seem obvious, or even that it could work.

331 This representation proves that $1j$ is not necessary to define a complex number. What $1j$ can
332 do is simplify the algebra, both conceptually and for numerical results. It is worth your time to
333 become familiar with the matrix representation, to clarify any possible confusions you might have
334 about multiplication and division of complex numbers. This matrix representation can save you time,
335 heartache and messy algebra. Once you have learned how to multiply two matrices, it's a lot simpler
336 than doing the complex algebra. In many cases we will leave the results of our analysis in matrix form,
337 to avoid the algebra altogether.²¹ More on this topic may be found in Chapter 2.

Real versus complex numbers: All numbers may be viewed as complex. Namely every real number is complex if we take the imaginary part to be zero (Boas, 1987). For example, $2 \in \mathbb{P} \subset \mathbb{C}$. Likewise every purely imaginary number (e.g., $0 + 1j$) is complex with zero real part. It follows that $2j \in \mathbb{P}j$. Integers are a subset of reals, which are a subset of complex numbers²² *Gaussian integers* are complex integers ($\mathbb{Z} \subset \mathbb{R} \subset \mathbb{C}$).²³ From the above discussion it should be clear that each of these different classes of number are nested in a hierarchy, in the following embeddings

$$\pi_k \in \mathbb{P} \subset \mathbb{N} \subset \mathbb{Z} \subset \mathbb{Z} \cup \mathbb{F} = \mathbb{Q} \subset \mathbb{Q} \cup \mathbb{I} = \mathbb{R} \subset \mathbb{C}.$$

338 The integers \mathbb{Z} and fractionals \mathbb{F} split the rationals ($\mathbb{Q} : \mathbb{Z} \cup \mathbb{F}$, $\mathbb{Z} \perp \mathbb{F}$), each of which is a subset of
339 the rationals ($\mathbb{Z} \in \mathbb{Q}$, $\mathbb{F} \subset \mathbb{Q}$). The rationals \mathbb{Q} and irrationals \mathbb{I} split the reals ($\mathbb{R} : \mathbb{Q} \cup \mathbb{I}$, $\mathbb{Q} \perp \mathbb{I}$), each
340 of which is a subset of the reals ($\mathbb{Q} \in \mathbb{R}$, $\mathbb{I} \in \mathbb{R}$).

341 The roots of polynomials x_k are complex ($x_k \in \mathbb{C}$), independent of the genus of the coefficients (e.g.,
342 real integer coefficients give rise to complex roots). Each genus plays an important role in algebra, with
343 prime numbers at the bottom (root of the tree) and complex numbers at the top. We shall explore this
344 further in Chaps. 2 and 3.

²⁰Chapter 2 discusses the definition of the phase, i.e., how is it computed (i.e., $\arctan(e^{\theta j})$, $\arctan2(x, y)$), and the importance of the unwrapped phase, as in the example $\delta(t - \tau) \leftrightarrow e^{-\tau j}$.

²¹Sometimes we let the computer do the final algebra, numerically, as 2x2 matrix multiplications.

²²The plural *complexes* (a double /s/) seems an unacceptable word in English.

²³It follows that integers are a subset of Gaussian integers (the imaginary or real part of the Gaussian integer may be zero).

345 Finally, note that complex numbers \mathbb{C} do not have “order,” meaning one cannot be larger, smaller
 346 or equal to another. It makes no sense to say that $j > 1$ or $j = 1$ (Boas, 1987). The real and imaginary
 347 parts and the magnitude and phase have order.

348 **History of complex numbers:** It is notable how long it took for complex numbers to be accepted
 349 (1851), relative to when they were first introduced by Bombelli (16th century CE). In fact, complex
 350 integers (aka, *Gaussian integers*) were accepted before non-integral complex numbers. Apparently real
 351 numbers (\mathbb{R}) were not accepted (i.e., proved to exist, thus mathematically defined) until even later. It
 352 took the development of *set theory* in the late 19th century to sort out a proper definition of the real
 353 number, due to the existence of irrational numbers.

354 **Computer Representations of $\mathbb{I}, \mathbb{R}, \mathbb{C}$:** When doing numerical work, one must consider how we may
 355 compute within the family of reals (i.e., irrationals). There can be no irrational number representation
 356 on a computers. IEEE floating point numbers, which are the international standard of computation,
 357 are actually rational approximations. The mantissa and the exponent are each integers, having sign
 358 and magnitude. The size of each integer depends on the precision of the number being represented.
 359 An IEEE floating-point number is rational because it has a mantissa integer multiplied by a base to
 360 the power of an exponent integer.

Floating point numbers contain irrational numbers, which must be approximate by rational numbers. This leads to the concept of *fractional representation*, which requires the definition of the *mantissa*, *exponent* and *base*. Numerical results must not depend on the base. For example, when using base ten²⁴

$$\pi \cdot 10^5 \approx 314159.27\dots = 3 \cdot 10^5 + 1 \cdot 10^4 + 4 \cdot 10^3 + \dots + 9 \cdot 10^0 + 2 \cdot 10^{-1} \dots$$

According to Matlab’s DEC2BIN() routine, the binary representation is

$$\pi \cdot 2^{17} \approx 131072_{10} \cdot 22/7 = 110,0100,1001,0010,0101_2,$$

where 1 and 0 are multipliers of powers of 2, which are then added together as follows

$$2^{18} + 2^{17} + 2^{14} + 2^{11} + 2^8 + 2^5 + 2^2 + 2^0.$$

361 In base 16 (i.e, hexadecimal) $2^{17} \cdot 22/7 = 2^{18} \cdot 8_{16}/7_{16}$.

362 One may keep track of the decimal point using the exponent, which in this case is a factor of 2^{17}
 363 $= 131072_{10}$. The concept of a number having a decimal point is replaced by an integer, having the
 364 desired precision, and a scale factor of any base (radix). This scale factor may be thought of as moving
 365 the decimal point to the right (larger number) or left (smaller number). The mantissa “fine-tunes” the
 366 value about a scale factor (the exponent).

367 Here is $x = 2^{17} \times 22/7$ at IEEE 754 full double precision, as computed by an IEEE-754 floating
 368 point converter²⁵ $x = 411940.5625_{10} = 2^{54} \times 1198372 = 010010,001,10010,010010,010010,010010_2 =$
 369 $0x48c92492_{16}$. The commas in the binary string of ones and zeros, are to help visualize the quasi-
 370 periodic nature of the bit-stream. The mantissa is 4793490_{10} and the exponent is 2^{18} . The numbers
 371 are stored in a 32 bit format, with 1 bit for sign, 8 bits for the exponent and 23 bits for the mantissa.
 372 Perhaps a more instructive number is $x = 4793490.0 = 01,001,010,100,100,100,100,100,100,100_2$
 373 $= 0x4a,924,924_{16}$ which has a repeating binary bit pattern of $((100))_3$, only broken by the scale factor
 374 $0x4a$. Another with even higher symmetry is $x = 6.344,131,191,146,9 \times 10^{-17} = 0x24,924,924_{16} =$
 375 $00,100,100,100,100,100,100,100,100,100_2$. In this example the repeating pattern is clear in the
 376 Hex representation as a repeating $((942))_3$. As before, the commas are to help with readability, and
 377 have no other meaning.

²⁴Base 10 is the natural world-wide standard simply because we have 10 fingers.

²⁵<http://www.h-schmidt.net/FloatConverter/IEEE754.html>

378 There are other important types of representations. As pairs of reals, complex numbers have similar
 379 approximate representations. An important representations of complex numbers is $e^z = \cosh(z) +$
 380 $j \sinh(z)$, which includes the famous formula of Euler $e^{j\theta} = \cos \theta + j \sin \theta$. Some of these concepts can
 381 be generalized to include vectors, matrices and polynomials.

382 **Integers and the Pythagoreans** The integer is the corner stone of the Pythagorean doctrine, so
 383 much so that it caused a fracture within the Pythagoreans when it was discovered that not all numbers
 384 are rational. The famous example is the isosceles triangle $1, 1, \sqrt{2}$, which lead to the next triangle
 385 $[1, 2, \sqrt{3}]$, etc. This is known as the Spiral of Theodorus: the short side is 1 and the hypotenuse is
 386 extended by one, using a simple compass-ruler construction.

387 There are right-triangles with integral lengths, the best known being $[3, 4, 5]$. Such triplets of
 388 integers $[a, b, c]$ that satisfy the Pythagorean formula (Eq. 1.1) are denoted *Pythagorean triplets*, which
 389 may be verified using Euclid's formula (Eq. 1.3).

390 To form triangles with perfect 90° angles, the lengths need to satisfy Eq. 1.1. Such triangles are
 391 also useful in constructing buildings or roads made from of bricks having a uniform size.

392 **Public-private key Security:** An important application of prime numbers is public-private key
 393 (RSA) encryption, essential for internet security applications (e.g., online banking). To send secure
 394 messages the security (i.e., utility) of the internet is dependent on key encryption.²⁶ Most people
 395 assume this is done by a personal login and passwords. Passwords are simply not secure, for many
 396 reasons. The proper method depends on factoring integers formed from products of primes having
 397 thousands of bits.²⁷ The security is based on the relative ease in multiplying large primes, but the
 398 virtual impossibility of factoring them.

399 When a computation is easy in one direction, but its inverse is impossible, it is called a *trap-door*
 400 *function*. We shall explore the reasons for this in Chapter 2. If everyone switched from passwords to
 401 public key encryption, the internet would be much more secure.

402 **Puzzles:** A third application of integers are imaginative problems that use integers. An example is
 403 the classic Chinese *Four stone problem*: "Find the weight of four stones that can be used with a scale
 404 to weigh any object (e.g., salt, gold) between 0, 1, 2, ..., 40 [gm]." As with the other problems, the
 405 answer is not as interesting as the method, since the problem may be easily recast into a related one.
 406 This type of problem can be found in airline magazines as entertain on a long flight. The solution to
 407 this problem is best cast as a linear algebra problem, with integer solutions. Again, once you know the
 408 trick, it is "easy."²⁸

409 1.2.2 Lec 3: The role of physics in mathematics

410 **Bells, chimes and Eigenmodes** Integers naturally arose in art, music and science. An example
 411 are the relations between musical notes, the natural eigenmodes (tones) of strings and other musical
 412 instruments. These relations were so common and well studied, it appeared that to understand the
 413 physical world (aka, the Universe), one needed to understand integers. This was a seductive view, but
 414 not actually correct. As will be discussed in Sections 1.3.1 and 3.1.1, it is best to view the relationship
 415 between acoustics, music and mathematics as historical, since these topics played such an important
 416 role in the development of mathematics. Also interesting is the role that integers seem to play in
 417 quantum mechanics, for much the same reasons.

²⁶One might say this is either: i) a key application of primes, or ii) it is primary application of keys. Its a joke.

²⁷It would seem that public key encryption could work by having two numbers with a common prime, and then by using Euclidean algorithm, that GCD could be worked out. One of the integers could be the public key and the second could be the private key. Given the difficulty of factoring the numbers into their primes, and ease of finding the GCD using Euclidean algorithm, a practical scheme may be possible. Ck this out.

²⁸When ever someone tells you something is "easy," you should immediately appreciate that it is very hard, but there is a concept, that once you learn, the difficulty evaporates.

418 Engineers are so accustomed to working with real (or complex) numbers, the distinction between
 419 real (i.e., irrational) and fractional numbers are rarely acknowledged. Integers on the other hand
 420 arise in many contexts. One cannot master programming computers without understanding integer,
 421 hexadecimal, octal, and binary representations, since all numbers in a computer are represented in
 422 numerical computations in terms of rationals ($\mathbb{Q} = \mathbb{Z} \cup \mathbb{F}$).

423 As discussed in Section 1.2.1, the primary reason integers are so important is their absolute precision.
 424 Every integer $n \in \mathbb{Z}$ is unique,²⁹ and has the *indexing property*, which is essential for making lists that
 425 are ordered, so that one can quickly look things up. The alphabet also has this property (e.g., a book's
 426 index). Other than for hexadecimal numbers, which for notional reasons use the alphabet, letters are
 427 equivalent to integers.

428 Because of the integer's absolute precision, the digital computer overtook the analog computer,
 429 once it was practical to make logic circuits that were fast. The first digital computer was thought
 430 to be the *Eniac* at the University of Pennsylvania, but it turned out that the code-breaking effort in
 431 Bletchley Park, England, under the guidance of Alan Turing, created the first digital computer (The
 432 Colossus) to break the WWII German "Enigma" code. Due to the high secrecy of this war effort, the
 433 credit was only acknowledged in the 1970s when the project was declassified.

434 There is zero possibility of analog computing displacing digital computing, due to the importance
 435 of precision (and speed). But even with binary representation, there is a non-zero probability of error,
 436 for example on a hard drive, due to physical noise. To deal with this, error correcting codes have been
 437 developed, to reduce the error by several orders of magnitude. Today this is a science, and billions of
 438 dollars are invested to increase the density of bits per area, to increasingly larger factors. A few years
 439 ago the terabyte drive was unheard of; today it is the standard. In a few years petabyte drives will
 440 certainly become available. It is hard to comprehend how these will be used by individuals, but they
 441 are essential for on-line (cloud) computing.

442 Fundamental theorems

443 Modern mathematics is build on a hierarchical construct of *fundamental theorems*, as summarized in
 444 Table 1.2. The importance of such theorems cannot be overemphasized. Every engineering student
 445 needs to fully appreciate the significance of these key theorems. If necessary, memorize them. But
 446 that will not do over the long run, as each and every theorem must be fully understood. Fortunately
 447 most students already know several of these theorems, but perhaps not by name. In such cases, it is a
 448 matter of mastering the vocabulary.

449 The theorems are naturally organized, starting with two theorems on prime numbers (Table 1.2).
 450 These may also be thought of in terms of Stillwell's three streams. For Stream 1 there is the *Fundamen-*
 451 *tal Theorem of Arithmetic* and the *Prime Number Theorem*. For Stream 2 there is the *Fundamental*
 452 *Theorem of Algebra* and Bézout's theorem, while for Stream 3 there are a host of theorems on calcu-
 453 lus, ordered by their dimensionality. Some of these theorems verge on trivial (e.g., the Fundamental
 454 Theorem of Arithmetic). Others are more challenging, such as the *Fundamental Theorem of Vector*
 455 *Calculus* and *Green's theorem*.

456 Complexity should not be confused with importance. Each of these theorems is, as stated, funda-
 457 mental. Taken as a whole, they are a powerful way of summarizing mathematics.

458 Stream 1: Prime Number theorems:

459 There are two fundamental theorems about primes,

- 460 1. *The Fundamental Theorem of Arithmetic*: This states that every counting number $n > 1 \in \mathbb{N}$
 461 may be uniquely factored into prime numbers. This raises the question of the meaning of *factor*
 462 (split into a product).

²⁹Check out the history of $1729 = 1^3 + 12^2 = 9^3 + 10^3$.

Table 1.2: *The Fundamental theorems of mathematics*

1. Fundamental theorems of:

(a) **Number Systems: Stream 1**

- Arithmetic
- Prime Number

(b) **Geometry: Stream 2**

- Algebra
- Bézout

(c) **Calculus: Stream 3^a**

- Leibniz \mathbb{R}^1
- Complex $\mathbb{C} \subset \mathbb{R}^2$
- vectors $\mathbb{R}^3, \mathbb{R}^n, \mathbb{R}^\infty$

2. Other key concepts:

- Complex analytic functions ([complex roots are finally accepted!](#))
 - Complex Taylor Series (complex analytic functions)
 - Region of convergence (ROC) of complex analytic series
 - Laplace transform, and its inverse
 - Causal time \implies complex frequency s
 - Cauchy Integral Theorem
 - Residue integration (i.e., Green's Thm in \mathbb{R}^2)
- Riemann mapping theorem (Gray, 1994; Walsh, 1973)
- Complex Impedance (Ohm's Law) Kennelly

^aFlanders, Harley (June–July 1973). “Differentiation under the integral sign.” *American Mathematical Monthly* 80 (6): 615-627. doi:10.2307/2319163. JSTOR 2319163.

463 2. *The Prime Number Theorem*: One would like to know how many primes there are. That is easy:
 464 $|\mathbb{P}| = \infty$. (The *cardinality*, or size of the set of primes, is infinite). The proper way of asking
 465 this questions is *What is the average density of primes, in the limit as $n \rightarrow \infty$?* This question
 466 was answered, for all practical purposes, by Gauss, who as a pastime computed the first million
 467 primes by hand. He discovered that, to a good approximation, the primes are equally likely on
 468 a log scale. This is nicely summarized by the jingle attributed to the mathematician Pafnuty
 469 Chebyshev

470 Chebyshev said, and I say it again: *There is always a prime between n and $2n$.*

471 (Stillwell, 2010, p. 585)

472 When the ratio (interval) of two frequencies (pitch) is 2, the relationship is called an *octave*. Thus we
 473 might say there is at least one prime per octave. This makes on wonder about the maximum number
 474 of primes per octave. In modern music the octave is further divided into 12 intervals called *semitones*
 475 (factors), equal to the $\sqrt[12]{2}$. The product of 12 semitones is an octave. Thus we must wonder how
 476 many primes there is per semitone?

477 **Stream 2: Fundamental theorem of Algebra**

478 This theorem states that every polynomial has at least one root. When that root is removed then the
 479 degree of the polynomial is reduced by 1. Thus when applied recursively, a polynomial of degree N
 480 has N roots.

481 Besides the Fundamental Theorem of Algebra, a second important theorem is Bézout's theorem,
 482 which is a generalization of the Fundamental Theorem of Algebra. It says³⁰ that the *composition* of
 483 two polynomials has degree equal to the product of the degrees of each polynomial. For example, if
 484 $P_3(x) = x^3$ and $P_5(x) = x^5$, then $P_3(P_5)(x) = (x^5)^3 = x^{15}$. It further states that when counting the
 485 N roots of a polynomial of degree N , one must include the imaginary roots, double roots and roots at
 486 infinity, some of which may difficult to identify.

487 **Stream 3: Fundamental theorems of calculus**

488 There are at least four theorems related to integral calculus:

Helmholtz image

Table 1.3: Summary of the fundamental theorems of integral calculus.

Name	Mapping	Description
<i>Leibnez</i>	$\mathbb{R}^1 \rightarrow \mathbb{R}^0$	Area under a real curve.
<i>Cauchy</i>	$\mathbb{C} \rightarrow \mathbb{C}^0$	Residue integration and analytic functions.
<i>Gauss's Law</i>	$\mathbb{R}^3 \rightarrow \mathbb{R}^2$	Conservation of mass and charge crossing a closed surface.
<i>Stokes</i>	$\mathbb{R}^3 \rightarrow \mathbb{R}^1$	Relates line integrals to the rate of change of the flux crossing an open surface.
<i>Green</i>	$\mathbb{R}^2 \rightarrow \mathbb{R}_0$	Special case of Stokes for a plane
<i>Helmholtz</i>		Every differentiable vector field may be decomposed into a dilatation and a rotation.

489 In Sections 1.5.3, 1.5.5 and 5.1.3 we will deal with each of the theorems for Stream 3, where we
 490 consider the several Fundamental theorems of integration, starting with Leibniz's formula for integra-
 491 tion on the real line (\mathbb{R}), then progressing to complex integration in the complex plane (\mathbb{C}) (*Cauchy's*
 492 *theorem*), which is required for computing the inverse Laplace transform. Then we discuss Gauss' and
 493 Stokes' Laws for \mathbb{R}^2 , with closed and open surfaces. One cannot understand Maxwell's equations,
 494 fluid flow, or acoustics without understanding these theorems. Any problem that deals with the wave
 495 equation in more than one dimension requires an understanding of these concepts. The derivation of
 496 the Kirchhoff voltage and current laws is based on these theorems.

497 **Other key concepts**

498 Besides the widely recognized fundamental theorems for the three streams, there are a number of
 499 equally important theorems that have not yet been labeled as "fundamental."³¹

500 The widely recognized *Cauchy Integral Theorem* is an excellent example, since it is a stepping stone
 501 to the *Fundamental Theorem of Complex Integral Calculus*. In Chapter 4 we clarify the contributions
 502 of each of these special theorems.

503 Once these Fundamental theorems of integration (Stream 3) have been mastered, the student is
 504 ready for the *complex frequency domain*, which takes us back to Stream 2 and the *complex frequency*
 505 *plane* ($s = \sigma + \omega j \in \mathbb{C}$). While the Fourier and Laplace transforms are taught in Mathematics courses,

³⁰Statements of the theorem speak of *intersections* and constructions of curves, rather than compositions. I find this somewhat confusing. For example, how does intersection differ from elimination, or construction from composition (Stillwell, 2010, p. 119)?

³¹It is not clear what it takes to reach this more official sounding category.

506 typically few physical connections are made, accordingly the concept of *complex frequency* is rarely
 507 mentioned. The *complex frequency domain* and *causality* are fundamentally related, and critical for
 508 the analysis of signals and systems.

509 Without the concept of time and frequency, one cannot develop an intuition for the Fourier and
 510 Laplace transform relationships, especially within the context of engineering and mathematical physics.

511 WEEK 2

512

513 1.2.3 Lec 4: Prime numbers

514 If someone came up to you and asked for a theory of counting numbers, I suspect you would look them
 515 in the eye with a blank stare, and start counting. It sounds like either a bad joke or a stupid question.
 516 Yet integers are rich topic, so the question is not even slightly dumb. It is somewhat amazing that
 517 even birds and bees can count. While I doubt birds and bees can recognize primes, cicadas and other
 518 insects only crawl out of the ground in multiples of prime years, (e.g., 13 or 17 year cycles). If you have
 519 ever witnessed such an event (I have), you will never forget it. Somehow they know. Finally, there is
 520 an analytic function, first introduced by Euler, based on his analysis of the Sieve, now known as the
 521 *Riemann zeta function* $\zeta(s)$, which is complex analytic, with its poles at the logs of the prime numbers.
 522 The exact relationship between the primes and the poles will be discussed in Sections 1.4.12 and 4.5.2.
 523 The properties of this function are truly amazing, even fun. It follows that primes are fundamental
 524 properties of the counting numbers, that the theory of numbers (and primes) is an important topic of
 525 study. Many of the questions, and some of the answers, go back to at least the time of the Chinese
 526 (Stillwell, 2010).

527 The most relevant question at this point is “Why are integers so important?” We addressed this
 528 question in Section 1.2.9. First we count with them, so we can keep track of “how much.” But there
 529 is much more to numbers than counting: We use integers for any application where absolute accuracy
 530 is essential, such as banking transactions (making change), and precise computing of dates (Stillwell,
 531 2010, p. 70) or location (I’ll meet you at location $L \in \mathbb{N}$ at time $T \in \mathbb{N}$), building roads or buildings
 532 out of bricks (objects of a uniform size). If you go to 34th street and Madison and they are at 33th
 533 and Madison, that’s a problem. To navigate we need to know how to predict the tides, the location of
 534 the moon and sun, etc. Integers are important because they are precise: Once a month there is a full
 535 moon, easily recognizable. The next day its slightly less than full.

536 Sieves

537 A recursive sieve method for finding primes was first devised by the Greek Eratosthenes,³² and sum-
 538 marized in Fig. 1.5.

- 539 1. Write $N - 1$ counting number from 2 to N (List)
- 540 2. Define loop index $k = 1$ and a multiplier $n \in \mathbb{N}$ denoted $n := \{2, \dots, N\}$.
- 541 3. The next number on the list is prime $\pi_k \in \mathbb{P}$
- 542 4. Remove (Cross out) all multiples $n \cdot \pi_n$ of π_k
- 543 5. $k = k + 1$: return to step 3.

544 Starting from the first prime $\pi_1 = 2$, one successively strikes out all the multiples of that prime.
 545 For example, starting from $\pi_1 = 2$ one strikes out $2 \cdot 2, 2 \cdot 3, 2 \cdot 4, 2 \cdot 5, \dots, 2 \cdot (N/2)$. By definition the

³²https://en.wikipedia.org/wiki/Sieve_of_Eratosthenes#Euler.27s_Sieve

546 multiples are products of the target prime (2 in our example) and every another integer ($n \geq 2$). All
 547 the even numbers are removed in the first iteration. One then considers the next integer not struck
 548 out (3 in our example), which is identified as the next (second) prime π_2 . Then all the $(N - 2)/2$
 549 non-prime multiples of π_2 are struck out. The next number which has not been struck out is 5, thus is
 550 prime π_3 . All remaining multiples of 5 are struck out (~~10~~, ~~15~~, ~~25~~, \dots). This process is repeated until
 551 all the numbers on the starting list have been processed.

552 As the word sieve implies, this sifting process takes a heavy toll on the integers, rapidly pruning
 553 the non-primes. In four loops of the sieve algorithm, all the primes below $N = 50$ are identified in **red**.
 554 The final set of primes is displayed at the bottom of Fig. 1.5.

1. Write N integers from 2 to $N - 1$. Let $k = 1$. The first element $\pi_1 = 2$ is a prime. Cross out $n \cdot \pi_n$: (e.g., $n \cdot \pi_1 = 4, 8, 16, 32, \dots$).

	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50

2. Let $k = 2, \pi_2 = 3$. Cross out $n\pi_k$ (6, 9, 12, 15, \dots):

	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50

3. Let $k = 3, \pi_3 = 5$. Corss out $n\pi_3$. (Cross out 25, 35).

	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20
21	22	23	24	25	26	27	28	29	30
31	32	33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48	49	50

4. Finally let $k = 4, \pi_4 = 7$. Remove $n\pi_4$: (Cross out 49). Thus there are 15 primes less than $N = 50$: $\pi_k = \{2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47\}$.

Figure 1.5: Sieve of Eratosthenes for the case of $N = 50$.

555 Once a prime greater than $N/2$ has been identified, we may stop, since twice that prime is greater
 556 than N , the maximum number under consideration. Once you have reached \sqrt{N} all the primes have
 557 been struck out (this follows from the fact that the next prime π_n is multiplied by an integer $n =$
 558 $1, \dots, N$). Once this number $n\pi_n > N$ the list has been exhausted, which must be $n < \sqrt{N}$.

559 There are various schemes for making the sieve more efficient. For example the recursion $n\pi_k =$
 560 $(n - 1)\pi_k + \pi_k$. could speed up the process, by replacing the multiply by an add by a known quantity.
 561 When using a computer, memory efficiency and speed are the main considerations.

562 The importance of prime numbers

563 Likely the first insight into the counting numbers starts with the sieve, shown in Fig. 1.5. A sieve
 564 answers the question “What is the definition of a prime number?” which is likely the first question to

565 be asked. The answer comes from looking for irregular patterns in the counting numbers, by playing
 566 the counting numbers against themselves.

567 A prime is that subset of positive integers $\mathbb{P} \in \mathbb{N}$ that cannot be factored. The number 1 is not a
 568 prime, for some non-obvious reasons, but there is no pattern in it since it is always a (useless) factor
 569 of every counting number.

570 To identify the primes we start from the first candidate on the list, which is 2 (since 1 is not a
 571 prime), and strike out all multiples by the counting numbers greater than 1 $[(n+1) \cdot 2 = 4, 6, 8, \dots]$.
 572 While not obvious, this is our first result, that 2 is a prime, since it has no other factors but 1 and
 573 itself. This leaves only the odd numbers. We need a notation to indicate this result so we shall set
 574 $\pi_1 = 2$, as the first prime.³³

575 **Two Fundamental Theorems of Primes:** Early theories of numbers revealed two fundamental
 576 theorems (there are many more than two), as discussed in Section 1.2.2. The first of these is the
 577 *Fundamental Theorem of Arithmetic*, which says that every integer greater than 1 may be uniquely
 578 factored into a product of primes (Eq. 2.1). Our demonstration of this is empirical, using Matlab's
 579 `factor(N)` routine, which delivers the prime numbers that compose N .³⁴ Typically the prime factors
 580 appear more than once, for example $4 = 2^2$. To make the notation compact we define the *multiplicity*
 581 β_k of each prime factor π_k (Eq. 2.1).

582 Each counting number is *uniquely* represented by a product of primes. There cannot be two integers
 583 with the same factorization. Once you multiply the factors out, the result is a unique N . Note that it's
 584 easy to multiply integers (e.g., primes), but nearly impossible to factor them. Factoring is not the same
 585 as dividing, as one needs to know what to divide by. Factoring means dividing by some integer and
 586 obtaining another integer with a zero remainder. This is what makes it so difficult (nearly impossible).

587 So the question remains: "What is the utility of the FTA?" which brings us to the topic of *internet*
 588 *security*. Unfortunately at this time I can not give you a proper summary of how it works. The full
 589 answer requires a proper course in number theory, beyond what is presented here.

590 The basic concept is that it is easy to construct the product of two primes, even very long primes
 591 having hundreds, or even thousands, of digits. It is very costly (but not impossible) to factor them.
 592 Why not use Matlab's `factor(N)` routine to find the factors? This is where *cost* comes in. The
 593 numbers used in RSA are too large for Matlab's routine to deliver an answer. In fact, even the largest
 594 computer in the world (such as the University of Illinois' super computer (NCSA Water) cannot do
 595 this computation. The reason has to do with the number of primes. If we were simply looking up a few
 596 numbers from a short list of primes, it would be easy, but the density of primes among the integers, is
 597 huge (see Section 2.1.1). This take us to the *Prime Number Theorem* (PNT). The security problem is
 598 the reason why these two theorems are so important: 1) Every integer has a unique representation as a
 599 product of primes, and 2) the number of primes is very dense (their are a very large number of them).
 600 Security reduces to the needle in the haystack problem, the cost of a search. A more formal way to
 601 measure the density is called the *entropy*, which is couched in terms of the probability of events, which
 602 in this case is "What is the probability of finding a prime between N and $2N$?"

603 Rational numbers \mathbb{Q}

604 The most important genus of numbers are the rational numbers since they maintain the utility of
 605 absolute precision, and they can approximate any irrational number (e.g., $\pi \approx 22/7$) to any desired
 606 degree of precision. However, the subset of rationals we really are interested in are the fractionals \mathbb{F} .
 607 Recall that $\mathbb{Q} : \mathbb{F} \cup \mathbb{Z}$ and $\mathbb{F} \perp \mathbb{Z}$. The fractionals are the numbers with the approximation utility,
 608 with arbitrary accuracy. Integers are equally important, but for a very different reason. All numerical

³³There is a potentially conflicting notation since $\pi(N)$ is commonly defined as the number of primes less than index N . Be warned that here we define π_n as the n^{th} prime, and $\Pi(N)$ as the number of primes $\leq N$, since having a convenient notation for the n^{th} prime is more important than for the number of primes less than N .

³⁴If you wish to be a Mathematician, you need to learn how to prove theorems. If you're an Engineer, you are happy that someone else has already proved them, so that you can use the result.

609 computing today is done with \mathbb{Q} . Indexing uses integers \mathbb{Z} , while the rest of computing (flow dynamics,
 610 differential equations, etc.) is done with the fractionals \mathbb{F} . Computer scientists are trained on these
 611 topics, and engineers need to be at least conversant with them.

612 **Irrational numbers: The cardinality of numbers may be ordered:** $|\mathbb{I}| \ggg |\mathbb{Q}| \gg |\mathbb{N}| = |\mathbb{P}|$

613 The real line may be split into the irrationals and rationals. The rationals may be further split into
 614 the integers and the fractionals. Thus, all is *not* integer. If a triangle has two integer sides, then the
 615 hypotenuse must be irrational ($\sqrt{2} = \sqrt{1^2 + 1^2}$). This leads us to a fundamental question: “Are there
 616 integer solutions to Eq. 1.1?” We need not look further than the simple example $\{3, 4, 5\}$. In fact this
 617 example does generalize, and the formula for computing an infinite number of integer solutions is called
 618 *Euclid’s Formula*, which we will discuss in Section 2.1.3.

619 However, the more important point is that the cardinality of the irrationals is much larger than
 620 any set other than the reals (i.e., complex numbers). Thus when we use computers to model physical
 621 systems, we are constantly needing to compute with irrational numbers. But this is impossible since
 622 every irrational numbers would require an infinite number of bits to represent it. Thus we must compute
 623 with rational approximations to the irrationals. This means we need to use the fractionals. In the end,
 624 we must work with the IEEE 754 floating point numbers,³⁵ which are fractionals, more fully discussed
 625 in Section 2.1.1.

626 1.2.4 Lec 5: Greatest common divisor (Euclidean algorithm)

627 The *Euclidean algorithm* is a method to find the greatest common divisor (GCD) k between two integers
 628 n, m , denoted $k = \text{gcd}(n, m)$, where $n, m, k \in \mathbb{N}$. For example $15 = \text{gcd}(30, 105)$ since when factored
 629 $(30, 105) = (2 \cdot 3 \cdot 5, 7 \cdot 3 \cdot 5) = 3 \cdot 5 \cdot (2, 7) = 15 \cdot (2, 7)$. The Euclidean algorithm was known to the
 630 Chinese (i.e., not discovered by Euclid) (Stillwell, 2010, p. 41).

631 **Why is the GCD important?** Computing the GCD is simple, whereas a full factoring is extremely
 632 expensive. The GCD is important precisely because of the fundamental difficulty of factoring large
 633 integers into their primes. This utility surfaces when the two numbers are composed of very large
 634 primes. When two integers have no common factors they are said to be *coprime*, thus their GCD is 1.
 635 The ratio of two integers which are coprime is automatically in *reduced form* (they have no common
 636 factors).

637 For example $4/2 \in \mathbb{Q}$ is not reduced since $2 = \text{gcd}(4, 2)$. Canceling out the common factor 2, gives
 638 the reduced form $2/1 = 2 \in \mathbb{N}$. Thus if we wish to form the ratio of two integers, first compute the gcd
 639 and remove it from the two numbers, then form the ratio. This assures the rational number is in its
 640 reduced form. If the GCD were 10^3 digits it is obvious that the common factor must be removed before
 641 any computation should proceed.

An example: Take the two integers $[873, 582]$. In factored form these are $[\pi_{25} \cdot 3^2, \pi_{25} \cdot 3 \cdot 2]$. Given
 the factors, we see that the largest common factor is $\pi_{25} \cdot 3 = 291$. When we take the ratio of the two
 numbers this common factor cancels

$$\frac{873}{582} = \frac{\cancel{\pi_{25}} \cdot \cancel{3} \cdot 3}{\cancel{\pi_{25}} \cdot \cancel{3} \cdot 2} = \frac{3}{2}.$$

642 Of course if we divide 582 into 873 this we will numerically obtain the answer $1.5 \in \mathbb{R}$. If the common
 643 factor is large, a floating point number in \mathbb{F} is returned, since all floating point numbers are in \mathbb{F} .
 644 But due to rounding errors, it may not be $3/2$. To obtain the exact answer, in \mathbb{F} , we need the GCD.
 645 Removing large common factors, without actually factoring the two numbers, has obvious practical
 646 utility.

³⁵IEEE 754: <http://www.h-schmidt.net/FloatConverter/IEEE754.html>.

Greatest Common Divisor: $k=\gcd(m,n)$

- Examples ($m, n, k \in \mathbb{Z}$):
 - $\gcd(13 \cdot 5, 11 \cdot 5) = 5$ (The common 5 is the gcd)
 - $\gcd(13 \cdot 10, 11 \cdot 10) = 10$ (The $\gcd(130, 110) = 10 = 2 \cdot 5$, is not prime)
 - $\gcd(1234, 1024) = 2$ ($1234 = 2 \cdot 617$, $1024 = 2^{10}$)
 - $\gcd(\pi_k \pi_m, \pi_k \pi_n) = \pi_k$
 - $k = \gcd(m, n)$ is the part that cancels in the fraction $m/n \in F$
 - $m/\gcd(m, n) \in \mathbb{Z}$
- Co-primes ($m \perp n$) are numbers with no common factors: i.e., $\gcd(m, n) = 1$
 - The gcd of two primes is always 1: $\gcd(13, 11) = 1$, $\gcd(\pi_m, \pi_n) = 1$
 - $m = 7 \cdot 13, n = 5 \cdot 19 \Rightarrow (7 \cdot 13) \perp (5 \cdot 19)$
 - If $m \perp n$ then $\gcd(m, n) = 1$
 - If $\gcd(m, n) = 1$ then $m \perp n$
- The GCD may be extended to polynomials: e.g., $\gcd(ax^2 + bx + c, \alpha x^2 + \beta x + \gamma)$
 - $\gcd((x-3)(x-4), (x-3)(x-5)) = (x-3)$
 - $\gcd(x^2 - 7x + 12, 3(x^2 - 8x + 15)) = 3(x-3)$
 - $\gcd(x^2 - 7x + 12, (3x^2 - 24x + 45)) = 3(x-3)$
 - $\gcd((x-2\pi)(x-4), (x-2\pi)(x-5)) = (x-2\pi)$ (Needs long division)

Figure 1.6: The Euclidean algorithm for finding the GCD of two numbers is one of the oldest algorithms in mathematics, and is highly relevant today. It is both powerful and simple. It was used by the Chinese during the Han dynasty (Stillwell, 2010, p. 70) for reducing fractions. It may be used to find pairs of integers that are coprime (their gcd must be 1), and it may be used to identify factors of polynomials by long division. It has an important sister algorithm called the continued fraction algorithm (CFA), that is so similar in concept that Gauss referred to the Euclidean algorithm as the “continued fraction algorithm” (Stillwell, 2010, p. 48).

647 **Euclidean algorithm:** The algorithm is best explained by a trivial example: Let the two numbers
 648 be 6, 9. At each step the smaller number (6) is subtracted from the larger (9) and the difference
 649 (the remainder) and the smaller numbers are saved. This process continues until the two resulting
 650 numbers are equal, at which point the GCD equals that final number. If we were to take one more
 651 step, the final numbers would be the gcd and zero. For our example step 1 gives $9-6=3$, leaving 6 and
 652 3. Step 2 gives $6-3=3$ and 3. Since the two numbers are the same, the $\text{GCD}=3$. If we take one more
 653 difference we obtain (3,0). We can easily verify this result since this example is easily factored (e.g.,
 654 $3 \cdot 3, 3 \cdot 2) = 3(3, 2)$. It may be numerically verified using the Matlab GCD command $\text{gcd}(6, 9)$, which
 655 returns 3.

656 In Chapter 2, Section 2.1.2 (p. 77), we shall describe two methods for implementing this procedure
 657 using matrix notation, and explore the deeper implications.

658 Coprimes

659 Related to the prime numbers are *co-primes*, which are integers that when factored, have no common
 660 primes. For example $20 = 5 \cdot 2 \cdot 2$ and $21 = 7 \cdot 3$ have no common factors, thus they are coprime. Coprimes
 661 $[m, n]$ may be indicated with the “perpendicular” notation $n \perp m$, spoken as “n is perpendicular (perp)
 662 to m.” One may use the GCD to determine if two numbers are coprime. When $\gcd(m, n) = 1$, m and
 663 n are coprime. For example since $\gcd(21, 20) = 1$ (i.e., $21 \perp 20$) they are coprime.

664 1.2.5 Lec 6: Continued fraction algorithm (CFA)

665 The Continued fraction algorithm was mentioned in Section 1.2.4 at the end of the discussion on
 666 the GCD. These two algorithms (CFA vs. GCD) are closely related, enough that Gauss referred to
 667 the Euclidean algorithm as the Continued fraction algorithm (i.e., the name of the CFA algorithm)

668 (Stillwell, 2010, P. 48). This question of similarity needs some clarification, as it seems unlikely that
 669 Gauss would be confused about such a basic algorithm.

670 In its simplest form the CFA starts from a real decimal number and recursively expands it as
 671 a fraction. It is useful for finding rational approximations to any real number. The GCD uses the
 672 Euclidean algorithm on a pair of integers $m > n \in \mathbb{N}$ and finds their greatest common divisor $k \in \mathbb{N}$.
 673 At first glance it is not clear why Gauss would call the CFA the Euclidean algorithm. One must assume
 674 that Gauss had some deeper insight into the relationship. If so, it would be valuable to understand.

675 In the following we refine the description of the CFA and give examples that go beyond the simple
 676 cases of expanding numbers. The CFA of any number, say x_0 , is defined as follows:

- 677 1. Start with $n = 0$ and input target (starting value) $x_0 \in \mathbb{R}$.
- 678 2. If $|x_n| \geq 1/2$ define $a_n = \text{round}(x_n)$, which rounds to the nearest integer.
- 679 3. $r_n = x_n - a_n$ is the remainder. If $r_n = 0$, the recursion terminates.
- 680 4. Define $x_{n+1} \equiv 1/r_n$ and return to step 2 (with $n = n + 1$).

An example: Let $x_0 \equiv \pi \approx 3.14159\dots$. Thus $a_0 = 3$, $r_0 = 0.14159$, $x_1 = 7.065 \approx 1/r_0$, and $a_1 = 7$.
 If we were to stop here we would have

$$\hat{\pi}_1 \approx 3 + \frac{1}{7 + 0.0625\dots} \approx 3 + \frac{1}{7} = \frac{22}{7}. \quad (1.2)$$

This approximation of $\pi \approx 22/7$ has a relative error of 0.04%

$$\frac{22/7 - \pi}{\pi} = 4 \times 10^{-4}.$$

For the second approximation we continue by reciprocating the remainder $1/0.0625 \approx 15.9966$ which
 rounds to 16, resulting in the second approximation

$$\hat{\pi}_2 \approx 3 + 1/(7 + 1/16) = 3 + 16/(7 \cdot 16 + 1) = 3 + 16/113 = 355/113.$$

681 Note that if we had truncated 15.9966 to 15, the remainder would have been much larger, resulting
 682 in a less accurate rational approximation. The recursion may continue to any desired accuracy as
 683 convergence is guaranteed.

Rational approximation examples

$$\begin{aligned} \frac{22}{7} &= [3; 7] && \approx \pi + O(1.3 \times 10^{-3}) \\ \frac{355}{113} &= [3; 7, 16] && \approx \pi + O(2.7 \times 10^{-7}) \\ \frac{104348}{33215} &= [3; 7, 16, -249] && \approx \pi + O(3.3 \times 10^{-10}) \end{aligned}$$

Figure 1.7: The expansion of π to various orders using the CFA, along with the order of the error of each rational approximation. For example $22/7$ has an absolute error ($|22/7 - \pi|$) of about 0.13%.

Notation: Writing out all the fractions can become tedious. For example, expanding e using the Matlab command `rat(exp(1))` gives the approximation

$$3 + 1/(-4 + 1/(2 + 1/(5 + 1/(-2 + 1/(-7))))).$$

684 A compact notation for this these coefficients of the CFA is $[3; -4, 2, 5, -2, -7]$. Note that the leading
685 integer may be indicated by an optional semicolon to indicate the decimal point. Unfortunately Matlab
686 does not support the bracket notation.

687 If the process is carried further, the values of $a_n \in \mathbb{N}$ give increasingly more accurate rational
688 approximations. If the floor rounding is used $\pi = [3; 7, 15, 1, 292, 1, 1, 1, 2, 1, 3, 1, \dots]$ whereas true
689 rounding gives $\pi = [3; 7, 16, -294, 3, -4, 5, -15, \dots]$, thus rounding introduces negative coefficients each
690 time a number rounds up.

691 When the CFA is applied and the expansion terminates ($r_n = 0$), the target is rational. When
692 the expansion does not terminate (which is not always easy to determine), the number is irrational.
693 Thus the CFA has important theoretical applications regarding irrational numbers. You may try this
694 yourself using Matlab's `rats(pi)` command. Also try the Matlab command `rat(1+sqrt(2))`.

695 One of the useful things about the procedure, besides its being so simple, are its generalizations,
696 one of which will be discussed in Section 2.1.2 (p. 77).

A *continued fraction expansion* can have a high degree of symmetry. For example, the CFA of

$$\frac{1 + \sqrt{5}}{2} = 1 + \frac{1}{1 + \frac{1}{1 + \dots}} = 1.618033988749895 \dots,$$

697 Here the lead term in the fraction is *always* 1 ($a_n = [1; 1, 1, \dots]$), thus the sequence will not terminate,
698 proving that $\sqrt{5} \in \mathbb{I}$. A related example is `rat(1+sqrt(2))`, which gives $[2; 2, 2, 2, \dots]$.

When expanding a target irrational number ($x_0 \in \mathbb{I}$), and the CFA is truncated, the resulting
rational fraction approximates the irrational target. For the example above, if we truncate at three
coefficients ($[1; 1, 1]$) we obtain

$$1 + \frac{1}{1 + \frac{1}{1+0}} = 1 + 1/2 = 3/2 = 1.5 = \frac{1 + \sqrt{5}}{2} + 0.118 + \dots$$

Truncation after six steps gives

$$[1, 1, 1, 1, 1, 1] = 13/8 \approx 1.6250 = \frac{1 + \sqrt{5}}{2} + .0070 \dots$$

699 Because all the coefficients are 1, this example converges very slowly. When the coefficients are large
700 (i.e., remainder small), the convergence will be faster. The expansion of π is an example of faster
701 convergence.

702 **In summary:** Every rational number $m/n \in \mathbb{F}$, with $m > n > 1$, may be uniquely expanded as a
703 continued fraction, with coefficients a_k determined using the CFA. When the target number is irrational
704 ($x_0 \in \mathbb{Q}$), the CFA does not terminate, thus each step produces a more accurate rational approximation,
705 converging in the limit as $n \rightarrow \infty$.

706 Thus the CFA expansion is an algorithm that can, in theory, determine when the target is rational,
707 but with an important caveat: one must determine if the expansion terminates. In cases where the
708 expansion produces a repeating coefficient sequence, it is clear that the sequence cannot terminate.
709 The fraction $1/3 = 0.33333 \dots$ is an example of such a target where the CFA will terminate.³⁶

710 WEEK 3

711

³⁶Taking the Fourier transform of the target number, represented as a sequence, could identify a periodic component. The number $1/7 = [[1, 4, 2, 8, 5, 7]]_6$ has a 50 [dB] notch at 0.8π [rad] due to its 6 digit periodicity, carried to 15 digits (Matlab precision), Hamming windows, and then zero padded to 1024 samples.

712 **1.2.6 Labor day**713 **1.2.7 Lec 7: Pythagorean triplets (Euclid's formula)**

Euclid's formula is a method for finding three integer lengths $[a, b, c] \in \mathbb{N}$, that satisfy Eq. 1.1. It is important to ask "Which set are the lengths $[a, b, c]$ drawn from?" There is a huge difference, both practical and theoretical, if they are from the real numbers \mathbb{R} , or the counting numbers \mathbb{N} . Given $p > q \in \mathbb{N}$, the three lengths $[a, b, c] \in \mathbb{N}$ of Eq. 1.1 are given by

$$a = p^2 - q^2, \quad b = 2pq, \quad c = p^2 + q^2. \quad (1.3)$$

This result may be directly verified, since

$$[p^2 + q^2]^2 = [p^2 - q^2]^2 + [2pq]^2$$

or

$$p^4 + q^4 + \cancel{2p^2q^2} = p^4 + q^4 - \cancel{2p^2q^2} + \cancel{4p^2q^2}.$$

714 Thus, this result is easily proven, given the solution. Construction the solution is more difficult.

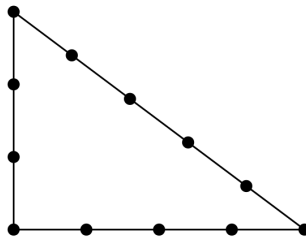

Figure 1.8: Beads on a string form perfect right triangles when number of beads on each side satisfy Eq. 1.1.

715 A well known example is the right triangle depicted in Fig. 1.8, defined by the integers $[3, 4, 5] \in \mathbb{N}$,
 716 having angles $[0.54, 0.65, \pi/2]$ [rad], which satisfies Eq. 1.1. As quantified by Euclid's formula Eq. 1.3
 717 (Section 2.2.1), there are an infinite number of *Pythagorean triplets* (PTs). Furthermore the seemingly
 718 simple triangle, having angles of $[30, 60, 90] \in \mathbb{N}$ [deg] (i.e., $[\pi/6, \pi/3, \pi/2] \in \mathbb{I}$ [rad]), has one irrational
 719 (\mathbb{I}) length $([1, \sqrt{3}, 2])$.

720 The technique for proving Euclid's formula for PTs $[a, b, c] \in \mathbb{Q}$, derived in Fig. 2.3 of Section 2.1.3,
 721 is much more interesting than the PTs themselves.

722 The set from which the lengths $[a, b, c]$ are drawn was not missed by the Indians, Chinese, Egyptians,
 723 Mesopotamians, Greeks, etc. Any equation whose solution is based on integers is called a *Diophantine*
 724 *equation*, named after the Greek mathematician Diophantus of Alexandria (c250 CE).

725 A stone tablet having the numbers engraved on it, as shown in Table 1.9 was discovered in
 726 Mesopotamia and from the 19th century [BCE] and cataloged in 1922 by George Plimpton.^{37, 38} These
 727 numbers are a and c pairs from PTs $[a, b, c]$. Given this discovery, it is clear that the Pythagoreans were
 728 walking in the footsteps of those well before them. Recently a second similar stone, dating between
 729 350 and 50 [BCE] has been reported, that indicates early calculus on the orbit of Jupiter's.³⁹

Figure 1.3: Pairs in Plimpton 322

1.2.1 For each pair (a, c) in the table, compute $c^2 - a^2$, and confirm that it is a perfect square, b^2 . (Computer assistance is recommended.)

You should notice that in most cases b is a “rounder” number than a or c .

1.2.2 Show that most of the numbers b are divisible by 60, and that the rest are divisible by 30 or 12.

Figure 1.9: “Plimpton-322” is a stone tablet from 1800 BCE, displaying a and c values of the Pythagorean triplets $[a, b, c]$. Numbers $(a, c \in \mathbb{N})$, with the property $b = \sqrt{c^2 - a^2} \in \mathbb{N}$, known as Pythagorean triplets, were found carved on a stone tablet from the 19th century [BCE]. Several of the c values are primes, but not the a values. The stone is item 322 (item 3 from 1922) from the collection of George A. Plimpton. –Stillwell (2010, Exercise 1.2)

731 with non-square $N \in \mathbb{N}$ specified and $a, b \in \mathbb{N}$ unknown, is related to the Euclidean algorithm (Stillwell,
732 2010, 48). For example, with $N = 2$, one solution is $a = 17, b = 12$ ($17^2 - 2 \cdot 12^2 = 1$). This equation
733 has a long history (Stillwell, 2010).

A 2x2 matrix recursion algorithmic, used by the Pythagoreans to investigate the $\sqrt{2}$,

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x_{n-1} \\ y_{n-1} \end{bmatrix}, \quad (1.5)$$

734 with $[1, 0]^T$, results in solutions of Pell’s equations (Stillwell, 2010, p. 44). Their approach was likely
735 motivated by the Euclidean algorithm (GCD, p. 33), since $y_n/x_n \rightarrow \sqrt{2}$ (Stillwell, 2010, p. 37,55).
736 Note that this is a composition method, of 2x2 matrices, since the output of one matrix multiply is the
737 input to the next.

738 **Asian solutions:** The first intended solutions of Pell’s was presented by Brahmagupta (c628), who
739 independently discovered the equation (Stillwell, 2010, p. 46). Bramagupta’s novel solution introduced
740 a different *composition method* (Stillwell, 2010, p. 69), and like the Greek result, these solutions were
741 incomplete.

742 Then in 1150CE, Bhâskara II obtained solutions using Eq. 1.5 (Stillwell, 2010, p.69). This is the
743 solution method we shall explore here, as summarized in Fig. 1.10.

The best way to see how this recursion results in solutions to Pell's equation, is by example. Initializing the recursion with the trivial solution $x_0 = [1, 0]^T$, gives

$$\begin{aligned} \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} && 1^2 - 2 \cdot 1^2 = -1 \\ \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} &= \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} && 3^2 - 2 \cdot 2^2 = 1 \\ \begin{bmatrix} x_3 \\ y_3 \end{bmatrix} &= \begin{bmatrix} 7 \\ 5 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ 2 \end{bmatrix} && (7)^2 - 2 \cdot (5)^2 = -1 \\ \begin{bmatrix} x_4 \\ y_4 \end{bmatrix} &= \begin{bmatrix} 17 \\ 12 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 5 \end{bmatrix} && 17^2 - 2 \cdot 12^2 = 1 \\ \begin{bmatrix} x_5 \\ y_5 \end{bmatrix} &= \begin{bmatrix} 41 \\ 29 \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 17 \\ 12 \end{bmatrix} && (41)^2 - 2 \cdot (29)^2 = -1 \end{aligned}$$

Thus the recursion results in a modified version of Pell's equation

$$x_n^2 - 2y_n^2 = (-1)^n,$$

744 thus only even values of n are solutions. This sign change had no effect on the Pythagoreans, who only
 745 cared about $y_n/x_n \rightarrow \sqrt{2}$.

746 **Solution to Pell's equation:** By multiplying the matrix by $1j$, all the solutions to Pell's equation
 747 are determined. This solution is shown in Fig. 1.10 for the case of $N = 2$, and again in Appendix D,
 748 Eq. D.1, for $N = 3$. The math is straightforward and is easily verified using Matlab. From Fig. 1.10
 749 we can see that every output this slightly modified matrix recursion gives solutions to Pell's equation
 750 (Eq. 1.4).

751 For $n = 0$ (the initial solution) $[x_0, y_0]$ is $[1, 0]$, $[x_1, y_1] = j[1, 1]$, and $[x_2, y_2] = -[3, 2]$. These are
 752 easily computed by this recursion, and easily checked on a hand calculator (or using Matlab). Without
 753 the j factor the sign would alternate; the $1j$ factor corrects the alternation in sign, so every iteration
 754 yields a solution.

- Case of $N = 2$ & $[x_0, y_0]^T = [1, 0]^T$
 Note: $x_n^2 - 2y_n^2 = 1$, $x_n/y_n \xrightarrow{\infty} \sqrt{2}$

$$\begin{aligned} \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} &= j \begin{bmatrix} 1 \\ 1 \end{bmatrix} = j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} && j^2 - 2 \cdot j^2 = 1 \\ \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} &= j^2 \begin{bmatrix} 3 \\ 2 \end{bmatrix} = j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} j \begin{bmatrix} 1 \\ 1 \end{bmatrix} && 3^2 - 2 \cdot 2^2 = 1 \\ \begin{bmatrix} x_3 \\ y_3 \end{bmatrix} &= j^3 \begin{bmatrix} 7 \\ 5 \end{bmatrix} = j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} j^2 \begin{bmatrix} 3 \\ 2 \end{bmatrix} && (7j)^2 - 2 \cdot (5j)^2 = 1 \\ \begin{bmatrix} x_4 \\ y_4 \end{bmatrix} &= \begin{bmatrix} 17 \\ 12 \end{bmatrix} = j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} j^3 \begin{bmatrix} 7 \\ 5 \end{bmatrix} && 17^2 - 2 \cdot 12^2 = 1 \\ \begin{bmatrix} x_5 \\ y_5 \end{bmatrix} &= j \begin{bmatrix} 41 \\ 29 \end{bmatrix} = j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 17 \\ 12 \end{bmatrix} && (41j)^2 - 2 \cdot (29j)^2 = 1 \end{aligned}$$

Figure 1.10: This summarizes the solution of Pell's equation for $N = 2$ using a slightly modified matrix recursion. Note that $x_n/y_n \rightarrow \sqrt{2}$ as $n \rightarrow \infty$, which was what the Pythagoreans were pursuing.

At each iteration, the ratio x_n/y_n approaches $\sqrt{2}$ with increasing accuracy, coupling it to the Euclidean algorithm (GCD). The value of $41/29 \approx \sqrt{2}$, with a relative error of $<0.03\%$. The solution for $N = 3$ is discussed at the end of Appendix D.

Relations to digital signal processing: Today we recognize Eq. 1.5 as a *difference equation*, which is a pre-limit (pre Stream 3) form of differential equation. The Greek 2x2 form is an early precursor to 17th and 18th century developments in linear algebra. Thus the Greek's recursive solution for the $\sqrt{2}$ and Bhâskara's (1030 CE) solution of Pell's equation, is an early precursor to discrete-time processing, as well as to calculus. Newton was fully aware of these developments as he reconstructed Diophantus chord/tangent method (Stillwell, 2010, p. 7, 49, 218).

Given the development of linear algebra c19th century, as discussed in Section 2.2.2 (page 83), this may be evaluated by eigenvector diagonalization.⁴⁰

There are similarities between Pell's Equation and the Pythagorean theorem. As we shall see in Chapter 2, Pell's equation is related to the geometry of a hyperbola, just as the Pythagorean equation is related to the geometry of a circle. One might wonder if there is a Euclidean formula for the solutions of Pell's Equations. After all, these are all conic sections with closely related geometry, in the complex plane.

Pell's Equation and irrational numbers: Since the eigenvalues of Eq. 1.5 ($\lambda_{\pm} = 1 \mp \sqrt{N} \notin \mathbb{N}$), solutions to Pell's equation raised the possibility that all numbers are not rational. This discovery of irrational numbers forced the jarring realization that the Pythagorean dogma "all is integer" was wrong. The significance of irrational numbers was far from understood.

WEEK 4

1.2.9 Lec 9: Fibonacci sequence

Another classic problem, formulated by the Chinese, was the Fibonacci sequence, generated by the relation

$$f_{n+1} = f_n + f_{n-1}. \quad (1.6)$$

Here the next number f_{n+1} is the sum of the previous two. If we start from $[0, 1]$, this difference equation leads to the Fibonacci sequence $f_n = [0, 1, 1, 2, 3, 5, 8, 13, \dots]$. The solution may be generated by the recursion of a 2x2 matrix equation, or by the z-transform method. Alternatively, if we define $y_{n+1} = x_n$, then

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix} \quad (1.7)$$

is equivalent to Eq. 1.6. The correspondence is easily verified. Starting with $[x_n, y_n]^T = [0, 1]^T$ we obtain for the first few steps

$$\begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad \begin{bmatrix} 2 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \quad \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \quad \dots$$

From the above $x_n = [0, 1, 1, 2, 3, 5, \dots]$ is the Fibonacci sequence since the next number is the sum of the last two.

Note that this 2x2 equation is similar to Pell's equation, suggesting that an eigenfunction expansion of Eq. 1.7 may be used to analyze the sequence, as shown in Section 2.3.1 (p. 83) (Stillwell, 2010, 192).

⁴⁰https://en.wikipedia.org/wiki/Transformation_matrix#Rotation

782 1.2.10 **Lec 10:** Exam I (In class)

WEEK 4-AE

12.5.0

783
784

- 785 L 11 Stream 2: Algebra and geometry as physics (Physics drives early mathematics)
 786 The first "algebra" (al-jabr) al-Khwarizmi (9th CE)
 787 Polynomial equations in one and two variables (Stillwell, 2010, Ch. 6, p. 87)
 788 Solution of the Quadratic Equation; Taylor series
 789 Composition and intersection of polynomials
 790 AE-1 (HW4) for 9/16/16; Add convolution problem. Verify due date.

791 1.3 Algebraic Equations: Stream 2

792 1.3.1 Lec 11 Algebra and geometry as physics

793 Following Stillwell's history of mathematics, Stream 2 is geometry, which led to the merging of Euclid's
 794 geometrical methods and the 9th century development of algebra by al-Khwarizmi (830 CE). This
 795 integration of ideas lead Descartes and Fermat to develop of *analytic geometry*. While not entirely a
 796 unique and novel idea, it was late in coming, given what was known at that time.

797 The mathematics up to the time of the Greeks, documented and formalized by Euclid, served
 798 students of mathematics for more than two thousand years. Algebra and geometry were, at first, inde-
 799 pendent lines of thought. When merged, the focus returned to the Pythagorean theorem, generalized as
 800 analytic conic sections rather than as geometry in Euclid's Elements. With the introduction of Algebra,
 801 numbers, rather than lines, could be used to represent a geometrical length. Thus the appreciation for
 802 geometry grew given the addition of the rigorous analysis using numbers.

803 **Physics inspires algebraic mathematics:** The Chinese used music, art, navigation to drive math-
 804 ematics. With the invention of algebra this paradigm did not shift. A desire to understand motions of
 805 objects and planets precipitated many new discoveries. Galileo investigated gravity and invented the
 806 telescope. Kepler investigated the motion of the planets. While Kepler was the first to appreciate that
 807 the planets were described by ellipses, it seems he under-appreciate the significance of this finding, and
 808 continued with his epicycle models of the planets. Using algebra and calculus, Newton formalized the
 809 equation of gravity, forces and motion (Newton's three laws) and showed that Kepler's discovery of
 810 planetary elliptical motion naturally follows from these laws. With the discovery of Uranus [in 1781]
 811 "Kepler's theory was ruined." (Stillwell, 2010, p. 23).

Once Newton proposed the basic laws of gravity, he proceed to calculate, for the first time, the speed of sound. This required some form of the *wave equation*

$$\frac{\partial^2}{\partial x^2} p(x, t) = \frac{1}{c^2} \frac{\partial^2}{\partial t^2} p(x, t), \quad (1.8)$$

812 a key equation in mathematical physics. The speed of sound is $c = 343$ [m/s], which is a function of
 813 the density $\rho = 1.12$ [kg/m³] and the dynamic stiffness ηP_0 of air.⁴¹

If we substitute for the pressure

$$p(x, t) = e^{j2\pi(ft \pm kx)}, \quad (1.9)$$

814 where t is time and x is position, we find that $(jk)^2 = s^2/c^2$, or $k = 2\pi/\lambda = 2\pi f/c$.

815 While Newton's value for c was incorrect by the thermodynamic constant $\sqrt{\eta}$, a problem that would
 816 take more than two hundred years to resolve, his success was important because it quantified the physics
 817 behind the speed of sound, and demonstrated that momentum mv , not mass m , was transported by the

⁴¹ $c = \sqrt{\eta P_0/\rho}$, $\eta = c_p/c_v = 1.4$ is the ratio of two thermodynamic constants, and $P_0 = 10^5$ [Pa] is the barometric pressure of air.

818 wave. His concept was correct, and his formulation using algebra and calculus represented a milestone
819 in science.

Newton's *Principia* was finally published in 1687, and the general solution to Newton's wave equation [i.e., $p(x, t) = G(t \pm x/c)$], where G is *any* function, was first published 60 years later by d'Alembert (c1747), which showed that for sounds of a single frequency, the wavelength λ and frequency f were related by

$$f\lambda = c.$$

820 Today d'Alembert's analytic wave solution is frequently written as Eq. 1.9 where $k = c/\lambda$ is the *wave*
821 *number*. This formulation led to the frequency domain concept of Fourier analysis, based on the
822 *linearity* (i.e., superposition) property of the wave equation (Postulate P2: Lec. 1.3.11, p. 61).

823 The corresponding discovery for the formula for the speed of light was made 114 years later by
824 Maxwell (c1861). Maxwell's formulation also required great ingenuity, as it was necessary to hypothesize
825 an experimentally unmeasured term in his equations, to get the mathematics to correctly predict the
826 speed of light.

The first Algebra: Prior to the invention of algebra, people worked out problems as sentences using an obtuse description of the problem (Stillwell, 2010, p. 93). Algebra solved this problem. Algebra may be thought of as a compact language, where numbers are represented as abstract symbols (e.g., x and α). The problems they wished to solve could be formulated in terms of sums of powers of smaller terms, the most common being powers of some independent variable (i.e., time or frequency). Today we call such an expression a *polynomial of degree n*

$$P_n(z) \equiv z^n + a_{n-1}z^{n-1} + \cdots + a_0z^0 = \sum_{k=0}^n a_k z^k = \prod_{k=0}^n (z - z_k). \quad (1.10)$$

827 Here we have set $a_n = 1$. The coefficient a_n cannot be zero, or the polynomial would not have degree
828 n . The solution is to force $a_n = 1$. This does not change the roots.

829 The key question was "What values of the $z = z_k$ result in $P_n(z_k) = 0$." In other words, what are
830 the roots z_k of the polynomial? The quest for the answer to this question consumed thousands of years,
831 with intense efforts by many aspiring mathematicians. In the earliest attempts, it was a competition
832 to evaluate mathematical acumen. Results were held as a secret to the death bed. It would be fair
833 to view this effort as an obsession. Today the roots of any polynomial may be found by numerical
834 methods, to very high accuracy. There are also a number of important theorems.

835 Of particular interest was composing a circle with a line, for example when the line does not touch
836 the circle, and finding the roots. There was no solution to this problem using geometry.

837 **Finding roots of polynomials** The problem of factoring polynomials has a history more than
838 a millennium in the making. While the quadratic (degree $N = 2$) was solved by the time of the
839 Babylonians (i.e., the earliest recorded history of mathematics), the cubic solution was finally published
840 by Cardano in 1545. The same year, Cardano's student solved the quartic ($N = 4$). In 1826 it was
841 proved that the quintic ($N = 5$) could not be factored by analytic methods.

As a concrete example we begin with trivial but important case of the quadratic

$$P_2(x) = ax^2 + bx + c. \quad (1.11)$$

The *roots* are those values of x such that $P_2(x_k) = 0$. One of the first results (recorded by the Babylonians, c2000 BCE) was the factoring of this equation by *completing the square* (Stillwell, 2010, p. 93). One may rewrite Eq. 1.11 as

$$\frac{1}{a}P_2(x) = (x + b/2a)^2 - (b/2a)^2 + c/a, \quad (1.12)$$

which is easily verified by expanding the squared term and canceling $(b/2a)^2$

$$\frac{1}{a}P_2(x) = [x^2 + (b/a)x + (b/2a)^2] - (b/2a)^2 + c/a.$$

Setting Eq. 1.12 to zero and solving for the two roots x_{\pm} , gives the *quadratic formula*⁴²

$$x_{\pm} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \quad (1.13)$$

842 If $b^2 + ac > 0$, then the two roots are real ($x_{\pm} \in \mathbb{R}$). Otherwise, they are complex. If $a, b, c \in \mathbb{R}$, which
843 is typically the case, then this condition simplifies to $ac < 0$ (i.e., $c/a > 0$).

844 No insight is gained by memorizing the quadratic formula (Eq. 1.13). On the other hand, an
845 important concept is gained by learning Eq. 1.12, which can be very helpful when doing analysis.
846 I suggest that instead of memorizing Eq. 1.13, memorize Eq. 1.12. Arguably, the factored form is
847 easier to remember (or learn). Perhaps more importantly, the term $b/2a$ has significance [$P_2(-b/2a) =$
848 $c/a - (b/2a)^2$], the sign of which determines if the roots are real or complex.

In third grade I learned the trick⁴³

$$9 \cdot n = (n - 1) \cdot 10 + (10 - n). \quad (1.14)$$

849 With this simple rule I did not need to depend on my memory for the 9 times tables. How one thinks
850 about a problem can have great impact.

Analytic Series: When the degree of the polynomial is infinite (i.e., $n = \infty$), $P_{\infty}(x)$, $x \in \mathbb{R}$ the series is called a *power series*. For values of x where the power series converges, it is said to be *analytic*. When the coefficients are determined by derivatives of $P(x)$ evaluated at $x = 0$, then it is called a *Taylor series*. These various series play a special role in mathematics, as the coefficients of the series uniquely determine a function (e.g., via the derivatives). Two well known examples are the geometric series

$$\frac{1}{1-x} = 1 + x + x^2 + x^2 + \dots = \sum_{n=0}^{\infty} x^n$$

and exponential

$$e^x = 1 + x + \frac{1}{2}x^2 + \frac{1}{3 \cdot 2}x^3 + \frac{1}{4 \cdot 3 \cdot 2}x^4 + \dots = \sum_{n=0}^{\infty} \frac{1}{n!}x^n.$$

Region of convergence: The set of values for which the series is analytic is called the *region of convergence*, or simply the ROC. Knowing how to determine the ROC for a given analytic function is quite important, and may not always be obvious. For the geometric series, the ROC is $|x| < 1$. The function $1/(x^2 + 1)$ has the same ROC as the geometric series, since it may be written as (Section A.6, p. 128)

$$\frac{1}{x^2 + 1} = \frac{1}{(x + 1j)(x - 1j)} = \frac{1}{2j} \left(\frac{1}{x - 1j} - \frac{1}{x + 1j} \right).$$

851 Each term has an ROC of $|x| < |1j| = 1$. In other words, it is the sum of two geometric series, each
852 having a pole at $\pm 1j$.

853 The exponential series converges for every finite value of x (the ROC is the entire open plane), thus
854 the exponential is called an *entire function*.

⁴²By direct substitution demonstrate that Eq. 1.13 is the solution of Eq. 1.11.

⁴³E.G.: $9 \cdot 7 = (7 - 1) \cdot 10 + (10 - 7) = 60 + 3$ and $9 \cdot 3 = 2 \cdot 10 + 7 = 27$. As a check note that the two digits of the answer must add to 9.

Analytic functions: Any function that has an analytic series representation is called an *analytic function*. Polynomials, $1/(1-x)$ and e^{x^j} are analytic functions. Because analytic functions are easily manipulated, term by term, they may be used to find solutions of differential equations. The derivatives are easily computed, since they may be uniquely determined, term by term. Every analytic function has a corresponding differential equation, that is determined by the coefficients of the analytic power series. An example is the exponential, which has the property that it is the eigenfunction of the derivative operation

$$\frac{d}{dx}e^{ax} = ae^{ax}.$$

This relationship is a common definition of the exponential function, which is a very special function. Analytic functions may also be easily integrated, term by term. Newton took full advantage of these properties of analytic functions. To fully understand the theory of differential equations (DE), one needs to master single valued analytic functions and their analytic power series. Newton used the analytic series (*Taylor series*) to solve many problems, especially for working out integrals, allowing him to solve DEs.

During the 16th and 17th century, it had becoming clear that DEs can characterize a law of nature at a single point in space and time. For example the law of gravity (first formulated by Galileo to explain the dropping to two objects of different masses) must obey conservation of energy. Newton (c1687) went on to show that there must be a gravitational potential between two masses (m_1, m_2) of the form

$$\phi(r) \propto \frac{m_1 m_2}{r}, \quad (1.15)$$

where $r = |x_1 - x_2|$ is the Euclidean distance between the two point masses at locations x_1 and x_2 . Note that this a power series, but with exponent of -1 , which is called a *pole*.

Single- vs. multi-valued functions: Polynomials are single valued functions: for each x there is a single value of $P_n(x)$. The set of x values of a function are called the *domain* and the set of $y(x)$ values are called the *codomain*. The roles of the domain and codomain may be swapped, to obtain the inverse function, which is typically quite different in its properties compared to the function. For example $y(x) = x^2 + 1$ has the inverse $x = \pm\sqrt{y-1}$, which is double valued, and complex when $y < 1$. Periodic functions such as $y(x) = \sin(x)$ are more exotic, since $x(y) = \arcsin(x) = \sin^{-1}(x)$ has an ∞ number of $x(y)$ values for each y .

Complex analytic functions: When the argument of an analytic function is complex, that is, $x \in \mathbb{R}$ is replaced by $z = x + jy \in \mathbb{C}$ (recall that $\mathbb{R} \in \mathbb{C}$), the function is said to be a *complex analytic*. We shall delve further into this topic in Section 3.1.1 (p. 87).

When the argument of the exponential becomes complex, it is periodic since

$$e^{st} = e^{(\sigma + j\omega)t} = e^{\sigma t} e^{j\omega t} = e^{\sigma t} [\cos(\omega t) + j \sin(\omega t)],$$

thus

$$\cos(\omega) = \frac{e^{j\omega} + e^{-j\omega}}{2}.$$

It should be clear that the exponential and circular functions are fundamentally related. This exposes the family of *entire circular functions* [i.e., $e^s, \sin(s), \cos(s), \tan(s), \cosh(s), \sinh(s)$] and their inverses [$\ln(s), \arcsin(s), \arccos(s), \arctan(s), \cosh^{-1}(s), \sinh^{-1}(s)$], first fully elucidated by Euler (c1750). Thus there is a deep relationship between single vs. multi-valued functions, periodic functions, functions of a complex variable, and their inverse functions, all of which are complex analytic. We shall explore this in Lec 1.3.8 (p. 56).

Given a complex analytic function of a complex variable, one must resort to the *extended complex plane*, *Riemann sheets* and *branch cuts*, as discussed in Section 1.3.7 (p. 54). The extended complex plane is a tool that is needed throughout complex analytic functions, and into higher mathematics,

Be sure this is a force).

882 since at least the 16th century, and probably before. This topic is critically important in engineering
 883 mathematics, and will be discussed in length in Sections 1.3.7-1.3.10 (pp. 54-59).

884 There seems to be some disagreement as to the status of multivalued functions: Are they functions,
 885 or is a function strictly single valued? If so, then we are missing out on a host of possibilities, including
 886 all the inverses of every complex analytic function.

887 **Impact on Physics:** It seems likely, if not obvious, that the success of Newton in mathematics was
 888 his ability to find mathematics in physics. He was inventing new mathematics at the same time as
 889 he was explaining new physics. The same might be said for Galileo. It seems likely that Newton was
 890 extending the successful techniques and results of Galileo. Galileo died on Jan 8, 1642, and Newton
 891 was born Jan 4, 1643, just short of one year later. Certainly Newton was well aware of Galileo's great
 892 success, and naturally would have been influenced by them.

893 The application of complex analytic functions to physics was dramatic, as may be seen in the six
 894 volumes on physics by Arnold Sommerfeld (1868-1951), and from the productivity of his many (36)
 895 students (e.g., Debye, Lenz, Ewald, Pauli, Guillemin, Bethe, Heisenberg⁴⁴ and Seebach, to name a
 896 few), notable coworkers (i.e., Leon Brillouin) and others (i.e., John Bardeen), upon whom he had a
 897 strong influence. Sommerfeld is known for having many students who were awarded the Nobel Prize in
 898 Physics, yet he was not (the prize is not awarded in Mathematics). Sommerfeld brought mathematical
 899 physics (the merging of physical and experimental principles with mathematics) to a new level with
 900 the use of complex integration of analytic functions to solve otherwise difficult problems, thus following
 901 the lead of Newton who used real integration of Taylor series to solve differential equations, and later
 902 Cauchy. While much of this work is outside the scope of the present discussion, it is helpful to know
 903 who did what and when, and how people and concepts are connected.

918 1.3.2 Lec 12 Physical equations quadratic in several variables

When lines and planes are defined, the equations are said to be *linear* in the independent variables. In keeping with this definition of *linear*, we say that the equations are *non-linear* when the equations have degree greater than 1 in the independent variables. The term *bilinear* has a special meaning, in that

⁴⁴<https://www.aip.org/history-programs/niels-bohr-library/oral-histories/4661-1>

both the domain and codomain are linearly related by lines (or planes). As an example, an impedance is defined in frequency as the ratio of the voltage over the current

$$Z(s) = \frac{V(\omega)}{I(\omega)} = \frac{N(s)}{D(s)},$$

919 where $Z(s)$ is the impedance and V and I are the voltage and current at radian frequency ω . The
 920 impedance is typically specified as the ratio of two polynomials, $N(s)$ and $D(s)$, as functions of complex
 921 Laplace frequency $s = \sigma + j\omega$. An example will be given in Section 1.3.6, Fig. 1.11. The bilinear
 922 function may be written as $D(s)V = N(s)I$. Since $D(s)$ and $N(s)$ are both polynomials in s , this
 923 is called bilinear. It comes from a corresponding scalar differential equation (Appendix A, Eq. A.1,
 924 p. 127).

925 As an example consider the well known problem in geometry: the intersection of a plane with a
 926 cone, which leads to the conic sections: the circle, hyperbola, ellipse and parabola, along with some
 927 degenerate cases, such as the intersection of two straight lines⁴⁵. If we stick to such 3-dimensional
 928 objects, we can write equations in the three variables $[x, y, z]$, and be sure that they each represent
 929 some physical geometry. For example $x^2 + y^2 + z^2 = r_0^2$ is a sphere of radius r_0 .

930 The geometry and the algebra do not always seem to agree. Which is correct? In general the
 931 geometry only looks at the real part of the solution, unless you know how to tease out the complex
 932 solutions. However the roots of any polynomial are from \mathbb{C} , so we may not ignore the imaginary roots,
 933 as Newton did. There is an important related fundamental theorems, known as Bézout's theorem, that
 934 address this case, as described next.

935 1.3.3 Lec 13: Polynomial root classification by convolution

936 Following the exploration of algebraic relationships by Fermat and Descartes, the first theorem was
 937 being formulated by d'Alembert. The idea behind this theorem is that every polynomial of degree N
 938 (Eq. 1.10) has at least one root. This may be written as the product of the root and a second polynomial
 939 of degree of $N - 1$. By the recursive application of this concept, it is clear that every polynomial of
 940 degree N has N roots. Today this result is known as the *Fundamental Theorem of Algebra*:

Every polynomial equation $p(z) = 0$ has a solution in the complex numbers. As Descartes observed, a solution $z = a$ implies that $p(z)$ has a factor $z - a$. The quotient

$$q(z) = \frac{p(z)}{z - a}$$

941 is then a polynomial of one lower degree. ... We can go on to factorize $p(z)$ into n linear
 942 factors.⁴⁶

943 —Stillwell (2010, p. 285).

944 The ultimate expression of this theorem is given by Eq. 1.10 (p. 43), which indirectly states that an
 945 n^{th} degree polynomial has n roots.

946 Today this theorem is so widely accepted we may fail to appreciate it. Certainly about the time you
 947 learned the quadratic formula, you were prepared to understand the concept. The simple quadratic case
 948 may be extended a higher degree polynomial. The Matlab/Octave command `roots([a3, a2, a1, a0])` will
 949 provide the roots of the cubic equation, defined by the four coefficients a_3, \dots, a_0 . I don't know the
 950 largest degree that can be accurately factored by Matlab/Octave, but I'm sure its well over $N = 10^3$.
 951 Today, finding the roots numerically is a solved problem.

⁴⁵Such problems were first studied algebraically and Descartes (Stillwell, 2010, p. 118) and Fermat (c1637).

⁴⁶Look into expressing this in terms of complex 2x2 matrices, as on p. 26.

952 **Factorization versus convolution:** The best way to gain insight into the polynomial factorization
 953 problem is through the inverse operation, multiplication of monomials. Given the roots x_k , there is
 954 a simple algorithm for computing the coefficients a_k of $P_n(x)$ for any n , no matter how large. This
 955 method is called *convolution*. Convolution is said to be a *trap-door* since it is easy, while the inverse,
 956 factoring (*deconvolution*), is hard, and analytically intractable for degree $N \geq 5$ (Stillwell, 2010, p. 102).

957 Convolution of monomials

958 As outlined by Eq. 1.10, a polynomial has two descriptions, first as a series with coefficients a_n and
 959 second in terms of its roots x_r . The question is “What is the relationship between the coefficients and
 960 the roots?” The simple answer is that they are related by *convolution*.

Let us start with the quadratic

$$(x + a)(x + b) = x^2 + (a + b)x + ab,$$

961 where in vector notation $[-a, -b]$ are the roots and $[1, a + b, ab]$ are the coefficients.

To see how the result generalizes, we may work out the coefficients for the cubic ($N = 3$). Multi-
 plying the following three factors gives

$$(x - 1)(x - 2)(x - 3) = (x^2 - 3x + 2)(x - 3) = x(x^2 - 3x + 2) - 3(x^2 - 3x + 2) = x^3 - 6x^2 + 11x - 6.$$

962 When the roots are $[1, 2, 3]$ the coefficients of the polynomial are $[1, -6, 11, -6]$. To verify, substitute
 963 the roots into the polynomial, and show that they give zero. For example $r_1 = 1$ is a root since
 964 $P_3(1) = 1 - 6 + 11 - 6 = 0$.

965 As the degree increases, the algebra becomes more difficult; even a cubic becomes tedious. Imagine
 966 trying to work out the coefficients for $N = 100$. What is needed is a simple way of finding the
 967 coefficients from the roots. Fortunately, *convolution* keeps track of the book-keeping, by formalizing
 968 the procedure.

Convolution of two vectors: To get the coefficients by convolution, write the roots as two vectors
 $[1, a]$ and $[1, b]$. To find the coefficients we must convolve the root vectors, indicated by $[1, a] \star [1, b]$,
 where \star denotes convolution. Convolution is a recursive operation. The convolution of $[1, a] \star [1, b]$ is
 done as follows: reverse one of the two monomials, padding unused elements with zeros. Next slide one
 monomial against the other, forming the local *dot product* (element-wise multiply and add):

$$\begin{array}{cccc} a & 1 & 0 & 0 \\ 0 & 0 & 1 & b \\ = & 0 & & \end{array} \quad \begin{array}{ccc} a & 1 & 0 \\ 0 & 1 & b \\ = & x^2 & \end{array} \quad \begin{array}{ccc} a & 1 & 0 \\ 1 & b & 0 \\ = & (a + b)x & \end{array} \quad \begin{array}{cccc} 0 & a & 1 & \\ 1 & b & 0 & \\ = & abx^0 & & \end{array} \quad \begin{array}{cccc} 0 & 0 & a & 1 \\ 1 & b & 0 & 0 \\ = & 0 & & \end{array},$$

969 resulting in coefficients $[\dots, 0, 0, 1, a + b, ab, 0, 0, \dots]$.

970 By reversing one of the polynomials, and then taking successive dot products, all the terms in the
 971 sum of the dot product correspond to the same power of x . This explains why convolution of the
 972 coefficients gives the same answer as the product of the polynomials.

As seen by the above example, the position of the first monomial coefficients are reversed, and then
 slid across the second set of coefficients, the dot-product is computed, and the result placed in the
 output vector. Outside the range shown, all the elements are zero. In summary,

$$[1, -1] \star [1, -2] = [1, -1 - 2, 2] = [1, -3, 2].$$

In general

$$[a, b] \star [c, d] = [ac, bc + ad, bd],$$

Convolving a third term $[1, -3]$ with $[1, -3, 2]$ gives

$$[1, -3] \star [1, -3, 2] = [1, -3 - 3, 9 + 2, -6] = [1, -6, 11, -6],$$

Table 1.4: Comparison between Euclidean Geometry and Algebra.

Geometry	Algebra	Property
y	y	Vector
y	y	Length
n	y	Complex Numbers
y	y	
y	y	
y	y	
y	y	
y	y	
y	y	

973 which is identical to the cubic example, found by the algebraic method.

974 By convolving one monomial factor at a time, the overlap is always two elements, thus it is never
 975 necessary to compute more than two multiplies and an add for each output coefficient. This greatly
 976 simplifies the operations (i.e., they are easily done in your head). Thus the final result is more likely
 977 to be correct. Comparing this to the algebraic method, convolution has the clear advantage.

978 **The product of monomial $P_1(x)$ with a polynomial $P_N(x)$ gives $P_{N+1}(x)$:** This statement is
 979 another way of stating the *Fundamental Theorem of Algebra*. Each time we convolve a monomial with
 980 a polynomial of degree N , we obtain a polynomial of degree $N + 1$. The convolution of two monomials
 981 results in a quadratic (degree 2 polynomial). The convolution of three monomials give a cubic (degree
 982 3). In general, the degree k , of the product of two polynomials, of degree n, m , is the sum of the degrees
 983 ($k = n + m$). For example, if the degrees are each 5 ($n = m = 5$), then the resulting degree is 10.

984 In summary, the product of two polynomials of degree m, n having m and n roots, give a polynomial
 985 of degree $m + n$ having $m + n$ roots. This is an analysis process, of merging polynomials, by coefficient
 986 convolution. Multiplying polynomials is a merging process, into a single polynomial.

987 Note that the degree of a polynomial is one less than the length of the vector of coefficients. The
 988 coefficient on the lead term should always be set to 1 since it cannot be zero, resulting in an illogical
 989 result. *Always* normalize the lead term of $P_n(x)$ to 1 (i.e., $a_N = 1$). This has no effect on the roots.

990 While you already know this theorem from high school algebra class, it is important to explicitly
 991 state the *Fundamental theorem of algebra*.

992 1.3.4 Lec 14: Introduction to Analytic Geometry

993 *Analytic geometry* is the natural consequence of Euclid's Geometry (which deals with conical geometry
 994 (e.g., points, lines, triangles, circles, spheres, ellipses, cones, etc., in two and three physical dimensions),
 995 merged with algebra (which deals with simultaneous equations, roots of polynomials, analytic functions,
 996 and ultimately, solutions of differential equations). The combination of Euclid's (323 BEC) geometry
 997 and al-Khwarizmi's (830 CE) algebra provides a new powerful tool, *analytic geometry*.

There are many important relationships between Euclidean Geometry and 16th century algebra.
 Important similarities include vectors, their Pythagorean lengths $[a, b, c]$

$$c = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}, \quad (1.16)$$

998 $a = x_2 - x_1$ and $b = y_2 - y_1$, and the angles. Geometry had no concept of coordinates of the vectors. This
 999 is one of the main differences, the ability of algebra to compute with numbers. A detailed comparison
 1000 is in order, attempted in Table 1.4.

1001 There are several basic concepts that merged under the development of analytic geometry

- 1002 1. Composition of functions: If $y = f(x)$ and $z = g(y)$ then the composition of functions f and g is
 1003 denoted $z(x) = g \circ f(x) = g(f(x))$.
- 1004 2. Elimination: Given two functions $f(x, y)$ and $g(x, y)$, elimination removes either x or y . This
 1005 procedure, called *Gaussian Elimination*, was known to the Chinese.
- 1006 3. Intersection: The intersection of curves define the roots of the common equations. Apparently
 1007 this involves composition followed by elimination.
- 1008 4. Vectors: Euclidean geometry includes the concept of a vector, as a line with a length and a slope.
 1009 Analytic geometry defines a vector as an ordered set of points.
- 1010 5. Analytic geometry extends the ideas of geometry with the introduction of the product of two
 1011 vectors, the dot product $\vec{f} \cdot \vec{g}$ and the cross product $\vec{f} \times \vec{g}$ (Appendix B).

What algebra added to geometry was the ability to compute with numbers. For example, the length of a line (Eq. 1.16) was measured in Geometry with a compass: numbers played no role. Once algebra was available, the line's Euclidean length could be computed from the coordinates of the two ends, defined by the *3-vector*

$$\vec{e} = x\hat{x} + y\hat{y} + z\hat{z},$$

1012 which represents a point at $(x, y, z) \in \mathbb{R}^3 \subset \mathbb{C}^3$ in three dimensions, having *direction*, from the origin
 1013 $(0, 0, 0)$ to (x, y, z) . A point, by itself, has no direction, thus is a scalar. An alternative matrix notation
 1014 is $\vec{e} = [x, y, z]^T$, a column vector of three numbers. These two notations are very different ways of
 1015 representing exactly the same thing. View them as equivalent concepts.

1016 By defining the vector, analytic geometry allows Euclidean geometry to become quantitative, be-
 1017 yond the physical drawing of an object (e.g., a sphere, triangle or line). With analytic geometry we
 1018 have the Euclidean concept of a vector, a line having a magnitude and direction (a slope), but in terms
 1019 of physical coordinates (i.e., numbers). The difference between two vectors defines a length, a concept
 1020 already present in Euclidean geometry, but not quantified other than by the spread of the compass
 1021 points placed at the two ends of the line.

Dot product of two vectors: When using algebra, many concepts in geometry are made precise. There are many examples of how algebra extends Euclidean geometry, the most basic being the *dot product* between two vectors

$$\begin{aligned} \vec{x} \cdot \vec{\zeta} &= (x\hat{x} + y\hat{y} + z\hat{z}) \cdot (\alpha\hat{x} + \beta\hat{y} + \gamma\hat{z}) \\ &= \alpha x + \beta y + \gamma z. \end{aligned}$$

The dot product takes two vectors in \mathbb{R}^3 and returns a real positive scalar function of the coordinates of the two vectors in \mathbb{R} , which represents a length. In matrix notation the dot product is written as

$$\vec{x} \cdot \vec{\zeta} = \begin{bmatrix} x \\ y \\ z \end{bmatrix}^T \begin{bmatrix} \alpha \\ \beta \\ \gamma \end{bmatrix} = [x, y, z] \begin{bmatrix} \alpha \\ \beta \\ \gamma \end{bmatrix} = \alpha x + \beta y + \gamma z.$$

1022 Recall that in matrix notation a vector, by default, is always a column. The transpose is a row-vector.

Norm of a vector: The *vector* $\vec{e} \in \mathbb{C}^3$ encompasses the scalar point (x, y, z) along with the scalar origin $(0, 0, 0) \in \mathbb{C}$, to define a the vector, having both a *magnitude*

$$\|\vec{e}\| = \sqrt{\vec{e} \cdot \vec{e}} = \sqrt{x^2 + y^2 + z^2},$$

and *direction* (i.e., three angles). The magnitude of the vector (its length) is given by the Pythagorean theorem, in \mathbb{R}^3 . Notationally, $\|\vec{e}\|$ is called the *norm* of the vector and is defined as the square root of dot product of the vector with itself. This is the generalization of a length, denoted the *norm* of \vec{e}

$$\|\vec{e}\| \equiv +\sqrt{\vec{e} \cdot \vec{e}}.$$

1023 The sign of the square-root must be positive as the length of a vector is not a concept from complex
1024 analytic functions. Rather the length is a concept of Euclidean geometry, and it must always be positive
1025 and real. A zero-length vector is a point, which has no direction (thus it is not a vector).

Add figure.

More generally, the Euclidean length of a line is given as the *norm* of the difference between two vectors

$$\begin{aligned} \|\vec{e}_1 - \vec{e}_2\|^2 &= (\vec{e}_1 - \vec{e}_2) \cdot (\vec{e}_1 - \vec{e}_2) \\ &= (x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2, \end{aligned}$$

1026 which is the Euclidean length between the two vectors. This length is not an analytic concept. Thus
1027 the minus sign on the root makes no sense in this context.

1028 **Cross product of two vectors:** The second type of product between two vectors is the cross-
1029 product $\vec{e}_1 \times \vec{e}_2$. While the dot product results in a scalar, the dot product results in a third vector,
1030 having a third component, not in the plane of the two being multiplied. The cross product results in a
1031 vector that points out of the plane defined by \vec{e}_1 and \vec{e}_2 . For example, if the two vectors are in \hat{x} and
1032 \hat{y} , then the cross-product has a component in \hat{z} . It is strictly in \hat{z} if the two vectors are perpendicular
1033 to each other (i.e., $\hat{z} = \hat{x} \times \hat{y}$).

The formula for computing the cross product is

$$\vec{x} \times \vec{\zeta} = (x\hat{x} + y\hat{y} + z\hat{z}) \times (\alpha\hat{x} + \beta\hat{y} + \gamma\hat{z}) = \begin{vmatrix} \hat{x} & \hat{y} & \hat{z} \\ x & y & z \\ \alpha & \beta & \gamma \end{vmatrix}.$$

1034 The cross product of a vector with itself (or the difference between two vectors) is zero.

1035 **Impact of Analytic Geometry:** The most obvious development, given the creation of analytic
1036 geometry, was a detailed analysis of the conic section, using algebra, rather than using drawings made
1037 with a compass and ruler. A useful example is the composition of the line and circle, a construction
1038 what was used many times over the history of mathematics. Once algebra was invented the composition
1039 could be done using formulas.

1040 The first two mathematicians to appreciate this mixture of Euclid's geometry and the new algebra
1041 were the French, Fermat and Descartes (Stillwell, 2010, p. 111-115); soon Newton contributed to this
1042 effort, by the addition of physics (calculations in acoustics, orbits of the planets, and the theory of
1043 gravity and light (Stillwell, 2010, p. 115-117).

1044 Given these new methods, many new solutions to problems emerged. The complex roots of poly-
1045 nomials continued to appear, without any obvious physical meaning. This seem to have been viewed
1046 as more of an inconvenience than a problem. Newton's solution to this dilemma was to simply ignore
1047 the imaginary cases (Stillwell, 2010, p. 119). The resolution of this was eventually to be found in
1048 Bézout's theorem, which states the number of roots of composition of two functions is determined by
1049 the product of their degrees. This problem is described as the *construct of equations* (Stillwell, 2010,
1050 p. 118). It was finally proved much later, by Bézout (1779), who showed how one needs to count all
1051 the roots, including multiple roots, and roots at infinity (Stillwell, 2010, p. 295).

1061 1.3.5 Lec 15 Gaussian Elimination

1062 The method for finding the intersection of equations is based on the recursive elimination of all the
 1063 variables but one. This method, known as *Gaussian elimination*, works across a broad range of cases,
 1064 but may be defined in a systematic procedure when the equations are linear in the variables.⁴⁷ Rarely
 1065 do we even attempt to solve problems in several variables of degree greater than 1. But Gaussian
 1066 eliminations can still work in such cases (Stillwell, 2010, p. 90).

In Appendix B the inverse of a 2x2 linear system of equations is derived. Even for a 2x2 case, the general solution requires a great deal of algebra. Working out a numeric example of Gaussian elimination is more instructive. For example, suppose we wish to find the intersection of the equations

$$\begin{aligned}x - y &= 3 \\ 2x + y &= 2.\end{aligned}$$

1067 This 2x2 system of equations is so simple that you may immediately see the solution: Adding the
 1068 two equations, and the y term is eliminated, giving $3x = 5$. But doing it this way takes advantage of
 1069 the specific example, and we need a method for larger systems of equations. We need a generalized
 1070 (algorithmic) approach. This general approach is *Gaussian elimination*.

Start by writing the equations in a standardized *matrix* format

$$\begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \end{bmatrix}. \quad (1.17)$$

Next, eliminate the lower left term ($2x$) using a scaled version of the upper left term (x). Specifically, multiply the first equation by -2, add it to the second equation, replacing the second equation with the result. This gives

$$\begin{bmatrix} 1 & -1 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 3 \\ 2 - 3 \cdot 2 \end{bmatrix} = \begin{bmatrix} 3 \\ -4 \end{bmatrix}. \quad (1.18)$$

1071 Note that the top equation did not change. Once the matrix is “upper triangular” (zero below the
 1072 diagonal) you have the solution. Starting from the bottom equation, $y = -4/3$. Then the upper
 1073 equation then gives $x - (-4/3) = 3$, or $x = 3 - 4/3 = 5/3$.

1074 In principle Gaussian elimination is easy, but if you make a calculation mistake along the way, it
 1075 is very difficult to find the error. The method requires a lot of mental labor, with a high probability
 1076 of making a mistake. You do not want to apply this method every time. For example suppose the
 1077 elements are complex numbers, or polynomials in some other variable such as frequency. Once the
 1078 coefficients become more complicated, the seeming trivial problem becomes highly error prone. There
 1079 is a much better way, that is easily verified, which puts all the numerics at the end in a single step.

The above operations may be automated by finding a carefully chosen upper-diagonalization matrix U that does the same operation. For example let

$$U = \begin{bmatrix} 1 & 0 \\ -2 & 1 \end{bmatrix}. \quad (1.19)$$

⁴⁷https://en.wikipedia.org/wiki/System_of_linear_equations

Multiplying Eq. 1.17 by U we find

$$\begin{bmatrix} 1 & 0 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ 2 \end{bmatrix}, \tag{1.20}$$

1080 we obtain Eq. 1.18. With a little practice one can quickly and easily find a U that does the job of
 1081 removing elements below the diagonal.

In Appendix B the inverse of a general 2x2 matrix is summarized in terms of three steps: 1) swap the diagonal elements, 2) reverse the signs of the off diagonal elements and 3) divide by the determinant $\Delta = ab - cd$. Specifically

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}^{-1} = \frac{1}{\Delta} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}. \tag{1.21}$$

1082 There are very few things that you must memorize, but the inverse of a 2x2 is one of them. It needs
 1083 to be in your tool-bag of tricks, as you once did for the quadratic formula.

While it is difficult to compute the inverse matrix from scratch (Appendix B), it takes only a few seconds to verify it (steps 1 and 2)

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} = \begin{bmatrix} ad - bc & -ab + ab \\ cd - cd & -bc + ad \end{bmatrix} = \begin{bmatrix} \Delta & 0 \\ 0 & \Delta \end{bmatrix}. \tag{1.22}$$

1084 Finally, dividing by the determinant gives the 2x2 identity matrix. A good strategy, when you don't
 1085 trust your memory, is to write down the inverse as best you can, and then verify.

Using 2x2 matrix inverse on our example, we find

$$\begin{bmatrix} x \\ y \end{bmatrix} = \frac{1}{1+2} \begin{bmatrix} 1 & 1 \\ -2 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} 5 \\ -6+2 \end{bmatrix} = \begin{bmatrix} 5/3 \\ -4/3 \end{bmatrix}. \tag{1.23}$$

1086 If you use this method, you will rarely (never) make a mistake, and the solution is easily verified.
 1087 Either you can check the numbers in the inverse, as was done in Eq. 1.22, or you can substitute the
 1088 solution back into the original equation.

1089 1.3.6 Lec 16: Transmission (ABCD) matrix composition method

1090 In this section we shall derive the method of composition of linear systems, known by several names
 1091 as the *ABCD Transmission matrix method*, or in the mathematical literature as the Möbius (bilinear)
 1092 transformation. By the application of the method of composition, a linear system of equations,
 1093 expressed in terms of 2x2 matrices, can represent a large family of differential equation networks.

1094 By the application of Ohm's law to the circuit shown in Fig. 1.11, we can model a cascade of such
 1095 cells. Since the CFA can also treat such circuits, as shown in Fig. 2.2 and Eq. 2.3, the two methods
 1096 are related to each other via the 2x2 matrix expressions.

Figure 1.11: This is a single LC segment of the transmission line show in Fig. 2.2. It may be modeled by the ABCD model as the product of two matrices, as show below. A more detailed analysis shows that the wave number is $\kappa = \sqrt{ZY} = \sqrt{sL \cdot sC} = s\sqrt{LC}$. It follows that the wave velocity is $c = 1/\sqrt{LC}$. The characteristic resistance is $r_c = \sqrt{Z/Y} = \sqrt{sL/sC} = \sqrt{L/C}$.

Example of the use of the ABCD matrix composition: In Fig. 1.11 we see the network is composed of a series inductor (mass) having an impedance $Z_l = sL$, and a shunt capacitor (compliance) having an impedance $Z_c = 1/sC$, where s is the Laplace frequency. By Ohm's Law, each impedance is describe by a linear relation between the current and the voltage. For the inductive impedance, applying Ohm's law, we find

$$V_1 - V_2 = Z_l I_1$$

where Z_l is the impedance of the inductor. For the capacitive impedance, applying Ohm's law we find

$$V_2 = (I_1 + I_2)Z_c,$$

where Z_c is the impedance of the capacitor. Each of these linear impedance relations may be written in matrix form. The series inductor equation gives

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} 1 & Z_l \\ 0 & 1 \end{bmatrix} \begin{bmatrix} V_2 \\ I_1 \end{bmatrix}, \quad (1.24)$$

while the shunt capacitor equation yields

$$\begin{bmatrix} V_2 \\ I_1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ Y_c & 1 \end{bmatrix} \begin{bmatrix} V_2 \\ I_2 \end{bmatrix}, \quad (1.25)$$

1097 where $Y_c = 1/Z_c$ is called the *admittance*.

When the second matrix equation for the capacitor is substituted into the inductor equation, we find the composite (factored) form ABCD matrix for the cell, as the product of two matrices

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} 1 & Z_l \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ Y_c & 1 \end{bmatrix} \begin{bmatrix} V_2 \\ I_2 \end{bmatrix} = \begin{bmatrix} 1 + Z_l Y_c & Z_l \\ Y_c & 1 \end{bmatrix} \begin{bmatrix} V_2 \\ I_2 \end{bmatrix}. \quad (1.26)$$

1098 For each matrix the input voltage and current are on the left (e.g., $[V_1, I_1]^T$), while the output voltage
1099 and current is on the right (e.g., $[V_2, -I_2]^T$). The sign of the output current must be negative, so that
1100 it is into the input node of the adjoining cell. In this way we may chain thes matrices together. On
1101 the left the input current is into the note. On the left the sign of the current (into the noted) must be
1102 reversed in sign, so that it will be into the node of the adjacent cell.

This represents a composition of 2x2 matrices, because the output of the second matrix is the input of the first. As discussed further in Section 3.3.2 (p. 98), the general expression is

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} V_2 \\ -I_2 \end{bmatrix}. \quad (1.27)$$

The ABCD matrix is also called the *chain matrix* method. The final equation (Eq. 1.26) characterizes the relations between the input and output voltage and current of the cell of Fig. 1.11 (p. 53). For example the ratio of the output to input voltage with the output unloaded ($I_2 = 0$) for the case of Eq. 1.26 is

$$\left. \frac{V_2}{V_1} \right|_{I_2=0} = \frac{1}{A} = \frac{1}{1 + Z_l Y_c} = \frac{Z_c}{Z_c + Z_l}.$$

1103 This is known as the *voltage divider equation*. Can you derive the formula for the current divider
1104 equation? Hint: $V_2 = 0$

1105 1.3.7 Lec 17: Riemann Sphere: 3^d extension of chord and tangent method

1106 Once algebra was formulated c830 CE, mathematics was able to expand beyond the limits placed on it
1107 by geometry on the real plane, and the verbose descriptions of each problem in prose (Stillwell, 2010,
1108 p. 93). The geometry of Euclid's Elements had paved the way, but after 2000 years, the addition of the

1109 language of algebra would change everything. The analytic function was a key development that had
 1110 served both Newton and Euler. Also the investigations of Cauchy made important headway with his
 1111 work on complex variables. Of special note was integration and differentiation in the complex plane of
 1112 complex analytic functions, which is the topic of stream 3.

1113 It was Riemann, working with Gauss, who made the breakthrough, with the concept of the *extended*
 1114 *complex plane*. The idea was based on the composition of a line with the sphere, similar to the derivation
 1115 of Euclid's formula for Pythagorean triplets. But the impact was unforeseen, and it changed analytic
 1116 mathematics forever, and the physics that was supported by it, by simplifying integrals to the extreme.
 1117 This idea is captured in the Fundamental Theorem of Complex Calculus (Sections 1.2.2 and 4.3.1).

Figure 1.12: The left panel shows how the real line may be composed with the circle. Each real x value maps to a corresponding point x' on the unit circle. The point $x \rightarrow \infty$ then naturally maps to the north pole N . This simple idea may be extended with the composition of the complex plane with the unit sphere, thus mapping the plane onto the sphere. As with the circle, the point on the complex plane $z \rightarrow \infty$ maps onto the north pole N . This construction is important because while the plane is open (does not include $z \rightarrow \infty$), the sphere is analytic at the north pole. Thus the sphere defines the closed extended plane. Figure from Stillwell (2010, pp. 299-300).

1118 The idea is outlined in Fig. 1.12. On the left is a circle and a line, the difference here is that the line
 1119 starts at the north pole and ends on the real $x \in \mathbb{R}$ axis, at point x . At point x' the line cuts through
 1120 the circle. Thus the mapping from x to x' takes every point on the real line to a point on the circle.
 1121 For example, the point $x = 0$ maps to the south pole (not indicated). To express x' in terms of x one
 1122 must composition of the line and the circle, similar to the composition used in Fig. 2.3. The points on
 1123 the circle, indicated here by x' , require a traditional polar coordinate system having a unit radius and
 1124 an angle defined between the radius a vertical line going through the north pole. When $x \rightarrow \infty$ the
 1125 point $x' \rightarrow N$, the north pole. The point at the north pole (on the circle) is called the *point at infinity*.
 1126 But this idea must to go further, as shown on the right half of Fig. 1.12.

1127 Here the real tangent line is replaced by the a tangent complex $z \in \mathbb{C}$ plane, and the puncture point
 1128 x' with a complex puncture point z' , in this case on the complex sphere, called the *extended complex*
 1129 *plane*. This is a natural extension of the chord/tangent method on the left, but with significant
 1130 consequences. The main difference between the complex plane z and the extended complex plane,
 1131 other than the coordinate system, is what happens at the north pole. On the plane the point at
 1132 $|z| = \infty$ is not defined, whereas on the sphere the point at the north pole is simply another point, like
 1133 every other point on the sphere.

1134 Mathematically the plane is said to be an *open set* since the limit $z \rightarrow \infty$ is not defined, whereas
 1135 on the sphere the z' is a *closed set* since the north pole is defined. The distinction between an open
 1136 and closed set is important because the closed set allows the function to be analytic at the north pole,
 1137 which it cannot be on the plane (since the point at infinity is not defined).

1138 The z plane may be replaced with another plane, say the $w = f(z) \in \mathbb{C}$ plane, where w is some
 1139 function f of $z \in \mathbb{C}$. We shall limit ourselves to *complex analytic functions* of z , namely $w = u(x, y) +$
 1140 $v(x, y)j = f(z) = \sum_{n=0}^{\infty} z^n$. In summary, given a point $z = x + yj$ on the open complex plane, we map
 1141 this using the function $w = f(z) \in \mathbb{C}$ to the complex $w = u + vj$ plane, and from there to the closed
 1142 extended complex plane $w'(z)$. The point of doing this is that it allows us to allow the function $w'(z)$
 1143 to be analytic at the north pole, meaning it can have a convergent Taylor series at $z \rightarrow \infty$.

1144 Möbius bilinear transformation

1145 In mathematics the *Möbius transformation* has special importance because it is linear in its action.
 1146 In the engineering literature this transformation is known as the *bilinear transformation*. Since we are
 1147 engineers we shall stick with the engineering terminology. But if you wish to read about this on the
 1148 internet, be sure to also search for the mathematical term, which may be better supported.

When a point on the complex plane $z = x + yj$ is composed with the bilinear transform ($a, b, c, d \in \mathbb{C}$), the result is $w(z) = u(x, y) + v(x, y)j$

$$w = \frac{az + b}{cz + d} \quad (1.28)$$

1149 the transformation is a cascade of four independent compositions

- 1150 1. translation ($w = z + b$)
- 1151 2. scaling ($w = |a|z$)
- 1152 3. rotation ($w = \frac{a}{|a|}z$) and
- 1153 4. inversion ($w = \frac{1}{z}$)

1154 Each of these transformations are a special case of Eq. 1.28, with the inversion the most complicated. A
 1155 wonderful video showing the effect of the bilinear (Möbius) transformation on the plane is available that
 1156 I highly recommended you watch it: Low resolution: <https://www.youtube.com/watch?v=0z1fIsUNh04>
 1157 High resolution: <https://www.ima.umn.edu/~arnold/moebius/moebius-movie.mov>

1158 When the extended plane (Riemann sphere) is analytic at $z = \infty$, one may take the derivatives
 1159 there, and one may meaningfully integrate through ∞ . When the bilinear transformation rotates the
 1160 Riemann sphere, the point at infinity is translated to a finite point on the complex plane, revealing
 1161 normal characteristics. A second way to access the point at infinity is by inversion, which takes the
 1162 north pole to the south pole, swapping poles with zeros. Thus a zero at infinity is the same as a pole
 1163 at the origin, and vice-versa.

1164 This construction of the Riemann sphere and the Möbius (bilinear) transformation allow us to fully
 1165 understand the point at infinity, and treat it like any other point. If you felt that you never understood
 1166 the meaning of the point at ∞ (likely), then this should help.

1167 WEEK 7

18.7.0

1168

1169 L 18 Colorized plots of complex analytic functions (Matlab *zviz.m*)

1170 L 19 Signals and Systems: Fourier vs. Laplace Transforms **AE-3**

1171 L 20 Role of Causality and the Laplace Transform:

1172 $u(t) \leftrightarrow 1/s$ (LT)

1173 $2\tilde{u}(t) \equiv 1 + \text{sgn}(t) \leftrightarrow 2\pi\delta(\omega) + 2/j\omega$ (FT)

1174 1.3.8 Lec 18: Complex analytic mappings (colorized plots)

1175 One of the most difficult aspects of com-
 1176 plex functions of a complex variable is un-
 1177 derstanding what's going on. For exam-
 1178 ple, $w = \sin(s)$ is trivial when $s = \sigma + j\omega$
 1179 is real, because $\sin(\sigma)$ is then real. But
 1180 $w(s) = \sin(s) \in \mathbb{C}$ not so easily visual-
 1181 ized when $s \in \mathbb{C}$, because such functions

Figure 1.13: On the left is a color map showing the definition of the complex s plane, with hue (darkness) indicating magnitude

1182 are mapping the $s = \sigma + \omega j$ plane to the
 1183 $w(\sigma, \omega) = u(\sigma, \omega) + v(\sigma, \omega)j$ plane.

1184 Every complex point from the s plane is
 1185 operated on by the function $F(s)$ to produce
 1186 a new complex point $w(s) = F(s)$. This
 1187 is typically difficult to understand the first
 1188 time you see it, thus requires a visualizing
 1189 method. Fortunately with computer soft-
 1190 ware today, this problem can be solved by adding color to the graph. A Matlab/Octave script `zviz.m`
 1191 was used to make these make the charts shown here.⁴⁸ By studying the function’s color map, one can
 1192 comprehend the complex mapping.

1193 We could look at $u(\sigma, \omega)$ and $v(\sigma, \omega)$ separately in black and white, but domain coloring allows us
 1194 to display everything on one plot. Note that for this visualization we see the polar form of $w(s)$ rather
 1195 than a rectangular (u, v) .

1196 Before we can give an example we must explain the color code being used for the magnitude and
 1197 phase of the complex plane. In Fig. 1.13 we show this code, as a 2x2 dimensional graph called “domain-
 1198 coloring.” The color allows us to visualize the magnitude and phase of the function. The color is used
 1199 to represent the phase and hue (dark to light) to represent the magnitude. On the left is the reference
 1200 condition given by the identity mapping ($w = s$). Red is 0° , violet is 90° , blue is 135° , blue-green is
 1201 180° and sea-green is -90° (or 270°). The hue (darkness) represents the magnitude. Since the function
 1202 $w = s$ has a zero at $s = 0$ it is dark there, and becomes brighter as we move away from the origin. The
 1203 figure on the right is $w = F(z - 1)$, which moves the zero point to the right by 1. As one would predict,
 1204 the zero has moved to the right by 1 unit, and the color has followed in line with the new location
 1205 of the zero. Colorized plots can give you a clear picture of the complex analytic function mappings
 1206 $w(x, y) = u(x, y) + v(x, y)j = F(x + yj)$.

Figure 1.14: On the left is the function $w(s) = e^s$ and on the right is $s = \log(w)$.

1207 Two examples are given in Fig. 1.14 to help you interpret the two complex mappings $w = e^s$ (left)
 1208 and its inverse $s = \ln(w)$. The exponential is very easy to understand because $w = e^\sigma e^{j\omega}$. The red
 1209 region is where $\omega \approx 0$ in which case $w \approx e^\sigma$. As σ becomes large and negative, $w \rightarrow 0$ so the entire
 1210 field at the left becomes dark. The field is becoming light on the right where $w = e^\sigma \rightarrow \infty$. If we let
 1211 $\sigma = 0$ and look along the ω axis, we see that the function is changing phase, green -90° at the top and
 1212 violet (90°) at the bottom.

1213 A really important point is the zero in $\ln(w)$ at $w = 1$. A little algebra clarifies this zero. The root

⁴⁸URL for `zviz.m`: <http://jontalle.web.engr.illinois.edu/uploads/298/zviz.m>

1214 of the log function is $\log(s_r) = 0$. Thus $s_r = 1$ since $\log(1) = 0$. More generally, letting $w = |w|e^{j\phi}$,
 1215 taking the log we find $s = \log(|w|) + j\phi$. Thus s can only be zero when the angle of w is zero ($\phi = 0$).

1216 1.3.9 Lec 19: Signals: Fourier transforms

1217 Two heavily used transformations in engineering mathematics are the Fourier and the Laplace trans-
 1218 forms, that are used for time–frequency domain analysis. They are not the same, but can be easily
 1219 confused as being related. Here we will clarify the differences and similarities.

1220 The Fourier and Laplace transforms take a (typically real) time domain signal $f(t) \in \mathbb{R}$ and trans-
 1221 form it to the frequency domain $F(\omega) \in \mathbb{C}$, where it is typically complex. For the Fourier transform,
 1222 both the time $-\infty < t < \infty$ and frequency $-\infty < \omega < \infty$ are strictly real.

1223 The Laplace transform takes signals that are strictly zero for negative time ($f(t) = 0$ for $t < 0$),
 1224 and transforms them into complex functions of complex frequency $s = \sigma + j\omega$. When a signal is zero
 1225 for negative time $f(t < 0) = 0$ is said to be *causal*. Any restriction on a function (e.g., real, causal,
 1226 positive real part, etc.) is called a *symmetry property*. There are many forms of symmetry.

1227 There is a very convenient notation for each of these two basic transformations, using a double-
 1228 arrow: $f(t) \leftrightarrow F(\omega)$ and $f(t) \leftrightarrow F(s)$, where the first is the Fourier transform $t \in \mathbb{R}$, $\omega \in \mathbb{R}$ with a
 1229 strictly real frequency, and the second is $t \geq 0 \in \mathbb{R}$, $s = \sigma + j\omega \in \mathbb{C}$, with complex *Laplace frequency*.

1230 Besides these two basic types of time to frequency transforms, there are several variants that
 1231 depend on the nature of the time and frequency representations. For example, when the time signal is
 1232 sampled (discrete in time), the frequency response becomes periodic. And the time response become
 1233 periodic, the frequency response is sampled (discrete in frequency). These two variants may be simply
 1234 characterized as *periodic in time* \Rightarrow discrete in frequency, and *periodic in frequency* \Rightarrow discrete in time.
 1235 In Section 3.4.2 we shall explain these concepts in greater detail, with examples.

1236 **Definition of the Fourier transform:** The definitions of the two transforms are similar, except
 1237 the time response for the Laplace transform is restricted to be causal and the frequency response of
 1238 the Fourier transform is restricted to be real.

$$F(\omega) = \int_{-\infty}^{\infty} f(t)e^{-j\omega t} dt \qquad \hat{f}(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} F(\omega)e^{j\omega t} d\omega \qquad (1.29)$$

$$F(\omega) \leftrightarrow f(t) \qquad \hat{f}(t) \leftrightarrow F(\omega) \qquad (1.30)$$

1239 Notes:

- 1240 1. Both time t and frequency ω are real.
- 1241 2. When taking the forward transform (from time to frequency) the sign of the exponential is
 1242 negative.
- 1243 3. The limits on the integrals in both the forward and reverse FTs are $[-\infty, \infty]$.
- 1244 4. When taking the inverse FT (IFT), the normalization factor of $1/2\pi$ is required to cancel the 2π
 1245 in the differential of the integral $d\omega/2\pi = df$, where f is frequency in [Hz], and ω is the radian
 1246 frequency.
5. The Fourier step function may be defined by the use of superposition of 1 and $\text{sgn}(t) = t/|t|$ as

$$\tilde{u}(t) \equiv \frac{1 + \text{sgn}(t)}{2} = \begin{cases} 1 & \text{if } t > 0 \\ 1/2 & t = 0 \\ 0 & \text{if } t < 0 \end{cases} .$$

The following is the derivation of this function assuming a delay of 1 [s]

$$\begin{aligned}\tilde{U}(\omega) &\equiv \int_{-\infty}^{\infty} \tilde{u}(t-1)e^{-j\omega t} dt \leftrightarrow \hat{u}(t-1) = \left\{ \frac{1 - \text{sgn}(t-1)}{2} \right\} = \pi\tilde{\delta}(\omega) + \frac{e^{-j\omega}}{j\omega} \\ &\neq \int_1^{\infty} e^{-j\omega t} dt = \left. \frac{e^{-j\omega t}}{-j\omega} \right|_1^{\infty} = \frac{e^{-j\omega} - e^{-j\omega\infty}}{j\omega} = \frac{e^{-j\omega}}{j\omega} - \frac{e^{-j\omega\infty}}{j\omega}\end{aligned}$$

- 1247 6. The convolution $\tilde{u}(t) \star \tilde{u}(t)$ has no meaning because $1 \star 1$ and $\tilde{\delta}^2(\omega)$ have no meaning.
- 1248 7. The inverse FT will have convergence problems whenever there is a discontinuity in the time
1249 response. This we indicate with a hat over the reconstructed time response. The error between
1250 the target time function and the reconstructed is zero in the root-mean sense, but not point-wise.
1251 Specifically, $\hat{u}(t) \neq u(t)$ but $\int |\hat{u}(t) - u(t)|^2 dt = 0$ near $t = 0$, the discontinuity point for the
1252 Fourier step function. At the point of the discontinuity the reconstructed function has Gibbs
1253 ringing (it does not converge at jumps). There are convergence issues with the IFT at jumps.
1254 More on this in Section 3.4.2.
- 1255 8. The FT is not complex analytic, as in the example of the step function. A function is not complex
1256 analytic if it does not have a Taylor series (in s). The step function cannot be expanded in a
1257 Taylor series about $\omega = 0$ because of the $\tilde{\delta}(\omega)$ term, which is not analytic.
9. The *delta function* is denoted $\tilde{\delta}(t)$ to differentiate it from the Laplace delta function $\delta(t)$. They differ because the step functions differ, due to the convergence problem described above. It follows that

$$\tilde{u}(t) = \int_{-\infty}^t \tilde{\delta}(t) dt.$$

One may also be consistent and define the somewhat questionable notation

$$\tilde{\delta}(t) =: \frac{d}{dt} \tilde{u}(t).$$

1258 1.3.10 Lec 20: Laplace transforms

1259 Lec 20: Signals (FT) versus Systems (LT): Fourier transforms for signals versus Laplace transforms for 1260 systems; Causality

1261 When dealing with engineering problems it is convenient to separate the signals we use from the
1262 systems that process them. We do this by treating signals, such as a music signal, differently from a
1263 system, such as a filter. In general signals may start and end at any time. The concept of causality
1264 has no physical meaning in signal space. Physical systems on the other hand obey very rigid rules (to
1265 assure that they remain physical). These Physical restrictions are described in terms of nine *Network*
1266 *Postulates*, which are discussed in some length in Lecture 1.3.11, and in greater detail in Section 3.5.1.
1267

Definition of the Laplace transform: The forward and inverse Laplace transforms are

$$F(s) = \int_{0^-}^{\infty} f(t)e^{-st} dt \qquad f(t) = \frac{1}{2\pi j} \int_{\sigma_0 - \infty j}^{\sigma_0 + \infty j} F(s)e^{st} ds \qquad (1.31)$$

$$F(s) \leftrightarrow f(t) \qquad f(t) \leftrightarrow F(s) \qquad (1.32)$$

1268 Notes:

- 1269 1. Time $t \in \mathbb{R}$. The complex Laplace frequency is defined as $s = \sigma + \omega j$.

- 1270 2. When taking the Forward transform (from time t to frequency s), the sign of the exponential is
 1271 negative. This is necessary to assure that the integral converges when the integrand $f(t) \rightarrow \infty$
 1272 as $t \rightarrow \infty$ (is diverging). For example, when $f(t) = e^t u(t)$ without the negative σ exponent, the
 1273 integral would not converge.
- 1274 3. The target time function must be zero for negative time (causal).
 1275 The time limits are $0^- < t < \infty$. Thus the integral must start from slightly below $t = 0$ to
 1276 integrate over any delta functions at $t = 0$. For example if $f(t) = \delta(t)$, the integral must include
 1277 both sides of the impulse. If you wish to include non-causal functions such as $\delta(t + 1)$ it is
 1278 necessary to extend the lower limit to pick them up. In such cases simply let the lower limit be
 1279 $-\infty$ and let the integrand determine the limits.
- 1280 4. The limits on the integrals of the forward are $t : (0^-, \infty)$ and reverse FTs are $[\sigma_0 - \infty j, \sigma_0 + \infty j]$.
 1281 These limits will be justified in Section 1.4.9.
- 1282 5. When taking the inverse FT (IFT), the normalization factor of $1/2\pi j$ is required to cancel the
 1283 $2\pi j$ in the differential ds of the integral.
- 1284 6. The frequency for the LT must be is complex, and in general $F(s)$ is complex analytic for $\sigma > \sigma_0$.
 1285 For example The real and imaginary parts of $F(s)$ are related, and given one, it may be possible
 1286 to find the other. More on this in Section 3.4.2.
- 1287 7. To take the inverse Laplace transform, we must learn how to integrate in the complex s plane.
 1288 This will be discussed in Section 4.3.1.
8. The Laplace step function is defined as

$$u(t) = \begin{cases} 1 & \text{if } t > 0 \\ \text{NaN} & t = 0 \\ 0 & \text{if } t < 0 \end{cases}$$

1289 and not defined at $t = 0$.

9. It is easily shown that $u(t) \leftrightarrow 1/s$ since

$$F(s) = \int_0^{\infty} u(t) e^{-st} dt = -\frac{e^{-st}}{s} \Big|_0^{\infty} = \frac{1}{s}.$$

1290 With the LT there is no Gibbs effect, as the step function, with a true discontinuity, is exactly
 1291 represented by the inverse LT.

$$\begin{aligned} f(t) &\leftrightarrow F(s) \\ \delta(t) &\leftrightarrow 1 \\ \delta(t - T_0) &\leftrightarrow e^{-sT_0} \\ u(t) &\leftrightarrow 1/s \\ u(t) \star u(t) = tu(t) &\leftrightarrow 1/s^2 \end{aligned}$$

- 1292 10. Frequently the Laplace transform takes the form of a ratio of two polynomials. In such case
 1293 the roots of the numerator polynomial are call the *zeros* while the roots of the denominator
 1294 polynomial are called the *poles*. For example the LT of $u(t) \leftrightarrow 1/s$ has a pole at $s = 0$.

1295 11. The LT is quite different from the FT in terms of its analytic properties, in the frequency domain.
 1296 For example, the step function $u(t) \leftrightarrow 1/s$ is not analytic everywhere except at the pole frequency
 1297 $s = 0$. In order to understand how this works we must define complex integration in the complex
 1298 plane, and thus justify the definition of the inverse LT (Eq. 1.31).

1299 **Disc relations between Fourier and Laplace delta and step functions**

1300 **WEEK 8**

20.8.0

1301

1302 **L 21 The 6 postulates of System (aka, Network) Theory; The important role of the Laplace transform**
 1303 **re impedance**

1304 **L 22 Exam II (Evening exam)**

1305 **1.3.11 Lec 21: The 9 postulates of systems**

1306 Systems of differential equations, such as the wave equation, need a mathematical statement of under-
 1307 lying properties, which we present here in terms of nine *network postulates*:

1308 (P1) *causality* (non-causal/acausal)

1309 (P2) *linearity* (nonlinear)

1310 (P3) *real* (complex) time response

1311 (P4) *passive* (active)

1312 (P5) *time-invariant* (time varying)

1313 (P6) *reciprocal* (non-reciprocal)

1314 (P7) *reversibility* (non-reversible)

1315 (P8) *space-invariant* (space-variant)

1316 (P9) *quasi-static* (multi-modal).

1317 Each postulate has two (in one case three) categories. For example for (P2) a system is either linear
 1318 or non-linear and for (P1) is either causal, non-causal or acausal. P6 and P9 only apply to 2-port
 1319 networks (those having an input and an output. The others can apply to both a 2- or 1-port networks
 1320 (e.g., an impedance is a 1-port).

1321 Related forms of these postulates had been circulating in the literature for many years, widely
 1322 accepted in the network theory literature (Van Valkenburg, 1964a,b; Ramo et al., 1965). But the first
 1323 six of these were formally introduced Carlin and Giordano (1964), while (P7-P9) were added by Kim
 1324 et al. (2016).

 1331 analytic
 1332 From Bernoulli to Euler to Cauchy and Riemann

1333 **1.4 Stream 3: Scalar (Ordinary) Differential Equations**

1334 Stream 3 is ∞ , a concept which inspires “very large,” which takes us to calculus, where ∞ actually
 1335 means “very small,” since taking a limit requires small numbers. Taking the limit means you never
 1336 reaching the target. This is a concept that the Greeks called *Zeno’s paradox* (Stillwell, 2010, p. 76).

1337 When speaking of the class of *ordinary* (versus *vector*) differential equations, the term *scalar* is
 1338 preferable, since the term “ordinary” is vague.

1339 There are a special subset of Fundamental theorems for scalar calculus, the first being Leibniz’s
 1340 theorem. These will be discussed in Sections 1.4.3, 4.2.2 and 4.3.2.

1360

1361 **1.4.2 Lec 24: Complex Analytic functions and the ROC**

To solve a differential equation, or integrate a function, Newton used the Taylor series to integrate one term at a time. However he only use real functions of a real variable due to the fundamental lack of understanding as to the meaning of a complex analytic series. This same method is the cornerstone of finding solutions to differential equations today, but in a “plug-and-chug” approach, that makes it less obvious how it works. Rather than working directly with the Taylor series, today we use the complex exponential. The reasoning is that the complex exponential is the eigenfunction of the derivative, namely

$$\frac{d}{dt}e^{st} = se^{st}.$$

1362 Thus a linear differential equation in time may be simply transformed into a polynomial in complex
 1363 Laplace frequency s , by looking for solutions of the form $A(s)e^{st}$. This substitution transforms the
 1364 differential equation into a polynomial $A(s)$ in complex frequency. The roots of $A(s)$ are the eigenvalues
 1365 of the original differential equation. Thus the keys to understanding the solutions of differential equa-
 1366 tions, both scalar and vector, is to work in the Laplace frequency domain.⁴⁹ The Taylor series has been
 1367 replaced by e^{st} , transforming Newton’s real Taylor series into the complex exponential eigenfunction.
 1368 In some sense, these are the same method.

This is heavily trodden soil, that every student now learns in the first course in scalar (ordinary) differential equations. However what the modern approach frequently ignores is the fundamental role of the complex power series, that is, the concept of the single-valued *complex analytic function* (Section 4.3.1. If a function $F(s)$ is complex analytic, then it has a power series

$$F(s) = \sum_0^{\infty} c_k s^k.$$

If we take the term by term derivative we find

$$\frac{d}{ds}F(s) = \sum_0^{\infty} k c_k s^{k-1},$$

1369 which is also complex analytic. Thus if the series for $F(s)$ is valid (i.e., it converges), then its derivative
 1370 is also valid, where it converges. This is a very powerful concept, fully exploited by Newton for real
 1371 functions of a real variable, and later by Cauchy and Riemann for complex functions of a complex
 1372 variable. The key here is “When does the series fail to converge?” in which case, the entire representa-
 1373 tion fails. This is the main message behind the *Fundamental Theorem of Complex Calculus*. The full
 1374 power of this concept was first exploited by Bernard Riemann (1826-1866) in his PhD Thesis of 1851
 1375 at University of Göttingen, under the tutelage of Carl Friedrich Gauss (1777-1855), drawing heavily
 1376 on the work of Cauchy.

1377 The key definition of a complex analytic function is that it has a Taylor series representation over
 1378 a region of the complex frequency plane $s = \sigma + j\omega$, that converges in a *region of convergence* (ROC),
 1379 about each pole of that function. A surprising feature of all analytic functions is that within the ROC,
 1380 the inverse of that function also has an analytic expansion. Thus given $w(s)$, one may also determine
 1381 $s(w)$ to any desired accuracy, critically depending on the ROC.

1382 This concept of analytic inverses becomes rich when the inverse function is multi-valued. For
 1383 example, if $F(s) = s^2$ then $s(F) = \pm\sqrt{F}$. Riemann dealt with such extensions with the concept of
 1384 a branch-cut with multiple planes, labeled by a branch number. Each branch describes an analytic
 1385 function (Taylor series) that converges within some ROC, with a radius out to the nearest pole of that
 1386 function. This explicitly dealt with the defining a unique inverse to multi-valued functions.

⁴⁹Make explicit the connection between the roots of the polynomial $A(s)$ and the eigenvalues of the matrix of the vector form of the same equation.

1387 **Complex impedance functions**

1388 One of the most obvious applications of complex functions of a complex variable an impedance. The
 1389 impedance function $Z(s) = R(\sigma, \omega) + jX(\sigma, \omega)$ has resistance R and reactance X , as a function of
 1390 complex frequency $s = \sigma + j\omega$. The function $z(t) \leftrightarrow Z(s)$ are defined by a Laplace transform pair.
 1391 From the causality postulate (P1) of Section 3.5.1, $z(t < 0) = 0$.

As an example, a resistor R_0 in series with an capacitor C_0 has an impedance

$$Z(s) = R_0 + 1/sC_0. \quad (1.33)$$

In mechanics a dash-pot (damper) and a spring have the same mechanical impedance. A resonant system has an inductor, resistor and a capacitor, with an impedance given by

$$Z(s) = R_0 + 1/sC_0 + sM_0 \quad (1.34)$$

1392 which is a second degree polynomial in the complex frequency s . Thus it has two roots (eigenvalues).
 1393 When $R_0 > 0$ these roots are in the left half s plane.

1394 Systems (networks) containing many elements, and transmission lines, can be much more compli-
 1395 cated, yet still have a simple frequency domain representation. This is the key to understanding how
 1396 these physical systems work, as will be described below.

1397 **1.4.3 Lec 25: Integration in the complex plane**

Leibniz's formula gives the area under a curve as the difference in the integral between the two limits such that the area only depends on the end points

$$F(x) = F(0) + \int_0^x f(\xi)d\xi. \quad (1.35)$$

This is based on a one-dimensional integration of real function $f(x)$ along the real x axis. As is well known,

$$\frac{d}{dx}F(x) = f(x)$$

1398 because the total area only depends on the end points for real areas $F(x)$.

For the complex case of an impedance, we define

$$F(s, t) = Z(s)e^{st}, \quad (1.36)$$

and the integrate in the complex plane, we may write a relation similar to the one-dimensional case

$$f(s) = f(0) + \int_0^s Z(s)e^{zt}dz. \quad (1.37)$$

Compare this to the real integral of the area over the real line x Eq. 1.35, Other than the limits, this formulas are the same as the Inverse Laplace transform. The integral can only dependent on the end points if

$$\frac{df}{ds} = F(s, t). \quad (1.38)$$

1399 But what does it man to take the derivative of a function with respect to s ?

1400 In the 1 dimensional case (Leibniz formula) the area only depends on the end points. It is interesting
 1401 to determine if, or when, this condition holds for complex integration. In the complex case the end
 1402 points are in the complex plane, which for example is z from $s = 0$ to s . Thus the condition is that if
 1403 the integral of $F(z, t)$ only depends on the end points ($[0, s]$) then it must be independent of the path
 1404 taken in the complex z plane.

1405 Many of these fundamental theorems of integration are closely related, in which case a teaching
 1406 moment is near. The best example is the relationship between the *Fundamental Theorem of Calculus*

1407 (aka Leibniz formula) and the *Fundamental Theorem of Complex Calculus* (aka, the Cauchy Integral
 1408 Theorem). The Leibniz formula Eq. 1.35 states that the area under a curve $f(x) \in \mathbb{R}$ only depends on
 1409 the end points. Equation 1.38 follows.

1410 Thus when the integral of $f(x)$ only depends on the limits, the function must be analytic. The
 1411 same holds true for the complex analytic case. When $f(x)$ is not analytic (has no Taylor series) the
 1412 derivative may not exist.

1413 1.4.4 Lec 26: Cauchy-Riemann conditions

For path independence the value of the integral ($f(s, t)$) must be the same for a path holding either σ or $j\omega$ constant. This leads to a pair of equations called the *Cauchy-Riemann* conditions in terms of the real and imaginary parts $F(s) = R(\sigma, \omega) + jX(\sigma, \omega)$ and $s = \sigma + j\omega$:

$$\frac{\partial R(\sigma, \omega)}{\partial \sigma} = j \frac{\partial X(\sigma, \omega)}{\partial j\omega} \quad \frac{\partial R(\sigma, \omega)}{\partial j\omega} = j \frac{\partial X(\sigma, \omega)}{\partial \sigma} \quad (1.39)$$

These are the necessary conditions that the integral of the function $F(s)$ is independent of the path, expressed in terms of the real and imaginary parts of the function and path. This assumption about the function is a very strong condition on $F(s)$ which requires that it may be written as a Taylor series in the complex argument s :

$$F(s) = F_0 + F_1 s + \frac{1}{2} F_2 s^2 + \dots \quad (1.40)$$

1414 Any function that may be expressed as a *Taylor series* about a point is said to be *complex analytic* at
 1415 that point. The series is said to converge within a *radius of convergence* (ROC). This highly restrictive
 1416 conditions has significant physical consequences. For example, every impedance function $Z(s)$ obeys
 1417 the CR conditions over large regions of the s plane, including the entire right half plane (RHP), defined
 1418 by $\sigma > 0$. When this conditions is generalize to volume integrals, it is called *Green's theorem*, which
 1419 is a special case of both Gauss's and Stokes's Laws, used heavily in the solution of boundary value
 1420 problems in Engineering-Physics (e.g., solving EM problems that start from Maxwell's equations). The
 1421 last third of this course shall depend heavily on this concept and various generalizations.

 1467 $x \in \mathbb{R}$ as his way of proving that the number of primes is infinite (Goldstein, 1973). In the end, this
 1468 formulation provided detailed information about the structure of the primes. The zeta function depends
 1469 explicitly on the primes, which is why it is interesting (Section 4.5.2).

1470 One might wonder why Euler's zeta function is known as the Riemann zeta function. It is because
 1471 Riemann showed its properties when the argument is complex, namely he extended $\zeta(s)$ into the
 1472 complex plane ($s \in \mathbb{C}$) (Section 4.5.2). Given that $\zeta(s)$ is a function of complex (Laplace) frequency,
 1473 one might naturally ask if $\zeta(s)$ has an inverse Laplace transform. There seems to be very little written
 1474 on this topic,⁵⁰ but we shall explore this interesting question further (Table 4.1). Perhaps even more
 1475 important is the taxonomy of $\zeta(s)$ is in question here, namely where are its poles and zeros? About
 1476 this there are volumes written.

1477 **The Riemann Zeta function is analytic with poles at log-primes**

1478 Why does the zeta function have zeros? Perhaps this is some extension of the Euler function that has
 1479 zeros, rather than zeta itself. Ask Andrew Odlyzko about this problem. Go to the Math dept first and
 1480 find someone qualified to discuss this with.

1514

1515 1.5.5 Lec 39 $\nabla, \nabla \cdot, \nabla \times$ & Vector operators

1516 There are three key vector differential operators that we need to understand Maxwell's equations. The
1517 *gradient* transforms a potential, such as a voltage $V(x, y, z)$ into a vector, such as the electric field
1518 vector \mathbf{E} . The *divergence* $\nabla \cdot \mathbf{E}(x, y, z)$ transforms a vector field into a scalar field. Finally the curl
1519 $\nabla \times \mathbf{A}(x, y, z)$ transforms a vector into a vector.

1520 To define these three operations we first need to define scalar and vector fields. These are concepts
1521 that you already understand. It is the terminology that needs to be mastered, not a new concept.
1522 Think of a voltage field in space, say between two finite sized capacitor plates. In such a case, the
1523 voltage is given by a *scalar field* $V(x, y, z)$. A scalar field is also called a *potential*. Somewhat confusing
1524 is that one may also define *vector potentials* which is three scalar potentials turned into a vector. So
1525 this term is more than one use. It is therefore important to recognize the intended use of the field.
1526 This can be gleaned from the units. Volts is a scalar field.

The simplest example of a scalar potential is the voltage between two very large (think ∞) conducting parallel planes, or plates (large so that we can ignore the edge effects). In this case the voltage varies linearly between the two plates. For example

$$V(x, y, z) = V_0(1 - x)$$

1527 is a scalar potential, thus it is scalar field (i.e., potential). At $x = 0$ the voltage is V_0 and at $x = 1$ the
1528 voltage is zero. Between 0 and 1 the voltage varies linearly. Thus $V(x, y, z)$ defines a *scalar field*.

1529 If the same setup were used but the two plates were 1×1 [cm²], with a 1 [mm] air gap, there will
1530 be a small “fringe” effect at the edges that would slightly modify the ideal fields. The hope is that
1531 this effect can be made small so that it does not ruin the capacitor composed of the two plates. If we
1532 are given a set of three scalar fields, we define a *vector field*. If the three elements of the vector are
1533 potentials, then we have a vector potential.

1534 Gradient operator ∇

The gradient operator takes a scalar fields and outputs a vector field. This is exactly what the gradient does. Given any scalar field $V(x, y, z)$ it outputs a vector field⁵¹

$$\mathbf{E}(x, y, z) = [E_x(x, y, z), E_y(x, y, z), E_z(x, y, z)]^T = -\nabla V(x, y, z).$$

1535 To understand these three operations we therefore need to define the domain and range of their
1536 operation, as specified in Table 5.1.

1537 1.5.6 Lec 40: Definitions of E, H, B, D and Maxwell’s equations

1538 Maxwell’s Equations

1539 Once you have mastered the three basic vector operations, the gradient, divergence and curl, you are
1540 able to understand Maxwell’s equations. Like the vector operations, these equations may be written
1541 in integral or vector form. The notation is basically the same since the concept is the same. The only
1542 difference is that with Maxwell’s equations we are dealing with well defined physical quantities. The
1543 scalar and vector fields take on meaning, and units. Thus to understand these important equations,
1544 one must master the units, and equally important, the names of the four fields that are manipulated
1545 by these equations.

1546 We may now restate everything defined above in terms of two types of vector fields that decompose
1547 every vector field. Thus another name for the Fundamental Theorem of Vector Calculus is the *Helmholtz*
1548 *decomposition*. An *irrotational field* is define as one that is “curl free,” namely the vector potential is a
1549 constant. An *incompressible field* is one that is “diverge free,” namely the scalar potential is a constant.
1550 Just to confuse matters, the incompressible field is also called a *solenoidal field*. I recommend that you
1551 know this term (as it is widely used), but never use it. Rather use incompressible as a more meaningful
1552 and physical term.

1553 1.5.7 Lec 41 Fundamental Theorem of Vector calculus (Helmholtz theorem)

1554 The Fundamental Theorem of Vector Calculus

1555 Here we define the basic vector operations based on the ∇ “operator,” the *gradient*, *divergence* and
1556 the *curl*. These operations may be defined in terms of integral operations on a surface in 1, 2 or 3
1557 dimensions, and then taking the limit as that surface goes to zero. These operators are required to
1558 understand Maxwell’s Equations, the crown jewel of mathematical physics.

⁵¹As before vectors are columns, which take up space on the page, thus we write them as rows and take the transpose to properly format them.

1559 Incompressible and Irrotational vector fields

1560 One of the most important fundamental theorems is that of vector calculus. This is also known as
 1561 *Helmholtz theorem*. This theorem is very easily stated but less easily to appreciate. But a physical
 1562 description of what is going on will help.

1563 A vector field may be split into two parts, that are independent. Think of linear and angular
 1564 momentum. They are also independent in that they represent different ways to store energy. An
 1565 object with mass can be moving along a path and rotating at the same time. The two modes of motion
 1566 define two different types of kinetic energy, translational and rotational. In some real sense, Helmholtz
 1567 theorem quantifies this independence.

The Fundamental Theorem of Vector Calculus: This theorem is also known as Helmholtz' theorem. It states that every differentiable vector field may be written as the sum of two terms, a scalar part and a vector part expressed in terms of a scalar potential $\phi(x, y, z)$ (think voltage) and a vector potential (think magnetic vector potential). Specifically

$$\mathbf{E} = -\nabla\phi + \nabla \times \mathbf{A}. \quad (1.41)$$

To show that this relationship splits the vector field \mathbf{E} into two parts we need to add to the mix two key vector identities, that are always true (assuming they exist, i.e, that the fields are differentiable):

$$\nabla \times \nabla\phi(x, y, z) = 0, \quad (1.42)$$

or in words, the *curl of the divergence* = 0, and

$$\nabla \cdot \nabla \times \mathbf{A} = 0 \quad (1.43)$$

1568 or the *divergence of the gradient* = 0. These identities are easily verified by working out a few examples
 1569 based on the definitions of the three operators, for example in terms of their integral definitions. They
 1570 also have an important physical meaning, as indicated above, that every vector field may be split into
 1571 its translational and rotational parts, as with our example of momentum.

1572 If we apply these two identities to Helmholtz's theorem
 1573 (Eq. 1.41), we can appreciate the significance of the theo-
 1574 rem. It is a form of proof actually, once you have satisfied
 1575 yourself that the vector identities are true. In fact one can
 1576 work backward using a physical argument, that rotational
 1577 momentum and thus energy is independent from transla-
 1578 tional momentum, thus energy. Again this all goes back to
 1579 the definitions of rotation and translational forces, hidden
 1580 in the vector operations. Once these forces are made clear,
 1581 the meaning of the vector operations all take on a very well
 1582 defined meaning, and the mathematical constructions, cen-
 1583 tered around Helmholtz's theorem, begins to provide some
 1584 common-sense meaning.

Specifically if we take the divergence of Eq. 1.41, and use the divergence vector identity

$$\nabla \cdot \mathbf{E} = \nabla \cdot \{-\nabla\phi + \nabla \times \mathbf{A}\} = -\nabla \cdot \nabla\phi = -\nabla^2\phi.$$

1585 since the divergence vector identity removes the vector po-
 1586 tential $\mathbf{A}(x, y, z)$.

Likewise if we take the curl of Eq. 1.41, and use the curl vector identity

$$\nabla \times \mathbf{E} = \nabla \times \{-\nabla\phi + \nabla \times \mathbf{A}\} = \nabla \times \nabla \times \mathbf{A},$$

H. v. Helmholtz.

Figure 1.15: von Helmholtz portrait taken from the English translation of his 1858 paper "On integrals of the hydrodynamic equations that correspond to Vortex motions" (in German) (von Helmholtz, 1978).

1587 since using the curl vector identity, removes the scalar field $\phi(x, y, z)$.

There is a third vector identity that needs to be mentioned for later use

$$\nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A}.$$

The best way to think of this relationship is that it *defines* the vector Laplacian $\nabla^2 \mathbf{A}$. In other words, think of this identity the definition of the left hand side of

$$\nabla^2 \mathbf{A} \equiv \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A}).$$

1601 1.5.8 Lec 42: Kirchoff's Laws and the quasistatic approximation

1602 - The term *quasistatics* indicates a type of approximation that is widely used when reducing a problem
1603 based on partial differential equations to one of a scalar differential equation. It is important to
1604 understand the nature of this approximation so that it is not miss-applied. Quasistatics is a way of
1605 reducing a three dimensional problem to a 1 dimensional problem. This approximation is at the heart
1606 of transmission line theory. Lets begin with an example: The acoustic wave equation describes how
1607 the scalar pressure $p(x, y, z, t)$ propagates in three dimensions. If the wave propagation is restricted
1608 to a pipe, such as an organ pipe, or to a string, as in a guitar string, we do not need to worry about
1609 the transverse directions. What needs to be modeled by the equations is the wave propagation along
1610 the pipe or string. Thus we replace the three-dimensional wave with a one-dimensional wave, without
1611 further thought.

1612 However if we wish to be more precise about this reduction in geometry, we need to consider
1613 the quasistatic approximation, as it makes some assumptions about what is happening in the other
1614 directions, and quantifies their effects. Taking the case of wave propagation in a tube, say the ear
1615 canal, there is the main wave direction, down the tube. But there is also wave propagation in the
1616 transverse direction, perpendicular to the direction of propagation. As shown in Table 3.1 (p. 107),
1617 the key statement of the quasistatic approximation is that the wavelength in the transverse direction
1618 is much larger than the radius of the pipe. This is equivalent to saying that the radial wave reaches the
1619 walls and is reflected back, in a time that is small compared to the distance propagated down the pipe.
1620 Clearly the speed of sound down the pipe and in the transverse direction is the same if the medium is
1621 homogeneous (i.e., air or water). Thus the sound reaches the walls and is returned to the center line
1622 in a time that the axial wave traveled about 1 diameter along the pipe. So if the distance traveled is

several diameters, the radial parts of the wave have time to come to equilibrium. So the question one must ask is, what are the conditions of such an equilibrium. The most satisfying answer to this is to look at the internal forces on the air, due to the gradients in the pressure.

The pressure $p(x, y, z, t)$ is a potential, thus its gradient is a force density $\mathbf{f}(x, y, z, t) = -\nabla p(x, y, z, t)$. What this equation tells us is that as the pressure wave approaches that of a plane wave, the radial (transverse) forces go to zero. If the tube has a curvature, or a change in area, then there will be local forces that create radial flow. But after traveling a few diameters, these forces will come to equilibrium and the wave will return to a plane wave. The internal stress caused by a change in area must settle out very quickly. There is a very important caveat however: it is only at low frequencies that the plane wave can dominate. At frequencies such that the wavelength is very small compared to the diameter, the distance traveled between reflections is much greater than a few diameters. Fortunately the frequencies where this happens are so high that they play no role in frequencies that we care about. This effect is referred to as *cross-modes* which imply some sort of radial standing waves. In fact such modes exist in the ear canal, but on the eardrum where the speed of sound is much slower than that of air. Because of the slower speed, the ear drum has cross-modes, and these may be seen in the ear canal pressure. Yet they seem to have a negligible effect on our ability to hear sound with good fidelity. The point here is that the cross modes are present, but we call upon the quasistatic approximation as a justification for ignoring them, to get closer to the first-order physics.

Breakdown of the quasistatic approximation at high frequencies: If we wonder, for the sake of wonderment, what happens at high frequencies where the quasistatic approximation begins to break down, we need to consider other significant physics of the system. In acoustics there are two basic effects that have been ignored by assuming that wave propagation is dictated by the wave equation, viscosity and thermal effects. In fact, it turns out that these two loss mechanisms are related, but to understand why is quite difficult. However Helmholtz, with some help from Kirchhoff, figured this out and published it between 1863 (Helmholtz, 1863b) and 1868 (Kirchhoff, 1868). Their theory was summarized by Lord Rayleigh (Rayleigh, 1896) and then experimentally verified to be correct by Warren P. Mason (Mason, 1928). The nature of the correction is that the wave number is extended to be of form

$$\kappa(s) = \frac{s + \beta_0\sqrt{s}}{c_0}, \quad (1.44)$$

where the forwarded P_- and backward P_+ pressure waves propagate as

$$P_{\pm}(s, x) = e^{-\kappa(s)x}, e^{-\bar{\kappa}(s)x} \quad (1.45)$$

and $\bar{\kappa}(s)$ is the complex conjugate of $\kappa(s)$, and $\Re\kappa(s) > 0$. The term $\beta_0\sqrt{s}$ affects both the real and imaginary parts of $\kappa(s)$. The real part is a frequency dependent loss and the imaginary part introduces a frequency dependent velocity (Mason, 1928).

The frequency where the loss-less part equals the lossy part is an important parameter of the system. This frequency is $s_0 + \beta_0\sqrt{s_0} = 0$, or $\sqrt{s_0} = -\beta_0$ or $f_0 = \beta_0^2/2\pi$.

Assuming air at 23.5° [C], $c_0 = \sqrt{\eta_0 P_0/\rho_0} \approx 344$ [m/s] is the speed of sound, $\eta_0 = c_p/c_v = 1.4$ is the ratio of specific heats, $\mu = 18.5 \times 10^{-6}$ [Pa-s] is the viscosity, $\rho_0 \approx 1.2$ [kgm/m³] is the density, $P_0 = 10^5$ [Pa] (1 atm).

The constant $\beta_0 = P\eta'/2S\sqrt{\rho_0}$

$$\eta' = \sqrt{\mu} \left[1 + \sqrt{5/2} \left(\eta^{1/2} - \eta^{-1/2} \right) \right]$$

is a thermodynamic constant, P is the perimeter of the tube and S the area (Mason, 1928).

For a cylindrical tube having radius $R = 2S/P$, $\beta_0 = \eta'_0/R\sqrt{\rho}$. To get a feeling for the magnitude of β_0 consider a 7.5 [mm] tube (i.e., the average diameter of the adult ear canal). Then $\eta' = 6.6180 \times 10^{-3}$ and $\beta_0 = 1.6110$. Using these conditions the wave-number cutoff frequency is $1.611^2/2\pi = 0.4131$ [Hz].

1653 At 1 kHz the ratio of the loss over the propagation is $\beta_0/\sqrt{|s|} = 1.6011/\sqrt{2\pi 10^3} \approx 2\%$. At 100 [Hz]
 1654 this is a 6.4% effect.⁵²

1655 Mason shows that the wave speed drops from 344 [m/s] at 2.6 [kHz] to 339 [m/s] at 0.4 [kHz], which
 1656 is a 1.5% reduction in the wave speed. In terms of the losses, this is much larger effect. At 1 [kHz]
 1657 the loss is 1 [dB/m] for a 7.5 [mm] tube. Note that the loss and the speed of sound vary inversely with
 1658 the radius. As the radius approaches the boundary layer thickness (the radial distance such that the
 1659 loss is e^{-1}), the effect of loss dominates.

1660 In Section 5.4.1 we shall look at some simple problems where we use the quasistatic effect and
 1661 derive the Kirchhoff voltage and current equations, starting from Maxwell's equations.

1662 1.5.9 Lec 43: Final Review for Final Exam

1663 Summary

1664 Mathematics began as a simple way of keeping track of how many things there were. But eventually
 1665 Physics and Mathematics evolved together as tools to help us navigate our environment, not just phys-
 1666 ically around the globe, but how to solve daily problems such as food, water and waste management,
 1667 understand the solar system and the stars, defend ourselves, use tools of war, etc.

1668 Based on the historical record of the abacus, one can infer that people precisely understood the
 1669 concept of counting, addition, subtraction and multiplication (recursive addition).

1670 There is some evidence that the abacus, a simple counting tool, formalizing the addition of very
 1671 large numbers, was introduced to the Chinese by the Romans, where it was used for trade.

1672 However this working knowledge of arithmetic did not to show up in written number systems. The
 1673 Roman numerals were not useful for doing calculations done on the abacus. The final answer would
 1674 then be expressed in terms of the Roman number system.

1675 According to the known written record, the number zero (null) had no written symbol until the
 1676 time of Brahmagupta (628 CE). One should not assume the concept of zero was not understood simply
 1677 because there was no symbol for it in the Roman Numeral system. Negative numbers and zero would
 1678 be obvious when using the abacus. Numbers between the integers would be represented as *rational*
 1679 *numbers* \mathbb{Q} since any number may be approximated with arbitrary accuracy with rations numbers.

1680 Mathematics is the science of formalizing a repetitive method into a set of rules, and then general-
 1681 izing it as much as possible. Generalizing the multiplication and division algorithm, to different types
 1682 of numbers, becomes increasingly more complex as we move from integers to rational numbers, irra-
 1683 tional numbers, real and complex numbers and ultimately, vectors and matrices. How do you multiply
 1684 two vectors, or multiply and divide one matrix by another? Is it subtraction as in the case of two
 1685 numbers? Multiplying and dividing polynomials (by long division) generalizes these operations even
 1686 further. Linear algebra is further important generalization, fallout from the Fundamental Theorem of
 1687 Algebra, and essential for solving the generalizations of the number systems.

1688 Many of the concepts about numbers naturally evolved from music, where the length of a string
 1689 (along with its tension) determined the pitch (Stillwell, 2010, pp. 11, 16, 153, 261). Cutting the string's
 1690 length by half increased the frequency by a factor of 2. One forth of the length increases the frequency
 1691 by a factor of 4. One octave is a factor of 2 and two octaves a factor of 4 while a half octave is $\sqrt{2}$. The
 1692 musical scale was soon factored into rational parts. This scale almost worked, but did not generalize
 1693 (sometimes known as *Pythagoreas' comma*⁵³), resulting in today's *well tempered scale*, which is based
 1694 on 12 equal geometric steps along one octave, or 1/12 octave ($\sqrt[12]{2} \approx 1.05946 \approx 18/17 = 1 + 1/17$).

1695 But the concept of a *factor* was clear. Every number may be written as either a sum, or a product
 1696 (i.e., a repetitive sum). This led the early mathematicians to the concept of a prime number, which is
 1697 based on a unique factoring of every integer. At this same time (c5000 BCE), the solution of a second
 1698 degree polynomial was understood, which lead to a generalization of factoring, since the polynomial, a
 1699 sum of terms, may be written in factored form. If you think about this a bit, it is sort of an amazing

⁵²/home/jba/Mimosa/2C-FindLengths.16/doc.2-c_calib.14/m/MasonKappa.m

⁵³https://en.wikipedia.org/wiki/Pythagorean_comma

1700 idea, that needed to be discovered (Stillwell, 2010, p.). This concept lead to an important string of
1701 theorems on factoring polynomials, and how to numerically describe physical quantities. Newton was
1702 one of the first to master these tools with his proof that the orbits of the planets are ellipses, not circles.
1703 This lead him to expanding functions in terms of their derivatives and power series. Could these sums
1704 be factored? The solution to this problem led to calculus.

1705 So mathematics, a product of the human mind, is a highly successful attempt to explain the physical
1706 world. All aspects of our lives were impacted by these tools. Mathematical knowledge is power. It
1707 allows one to think about complex problems in increasingly sophisticated ways. An equation is a
1708 mathematical sentence, expressing deep knowledge. Witnessed $E = mc^2$ and $\nabla^2\psi = \ddot{\psi}$.

1709 **Reading List:** The above concepts come straight from mathematical physics, as developed in the
1710 17th–19th centuries. Much of this was first developed in acoustics by Helmholtz, Stokes and Rayleigh,
1711 following in Green’s footsteps, as described by Lord Rayleigh (1896). When it comes to fully appre-
1712 ciating Green’s theorem and reciprocity, I have found Rayleigh (1896) to be a key reference. If you
1713 wish to repeat my reading experience, start with Brillouin (1953), followed by Sommerfeld (1952);
1714 Pipes (1958). Second tier reading contains many items: Morse (1948); Sommerfeld (1949); Morse
1715 and Feshbach (1953); Ramo et al. (1965); Feynman (1970); Boas (1987). A third tier might include
1716 Helmholtz (1863a); Fry (1928); Lamb (1932); Bode (1945); Montgomery et al. (1948); Beranek (1954);
1717 Fagen (1975); Lighthill (1978); Hunt (1952). You must enter at a level that allows you to understand.
1718 Successful reading of these books critically depends on what you already know. A rudimentary (high
1719 school) level of math comprehension must be mastered first. Read in the order that helps you best
1720 understand the material.

1721 Without a proper math vocabulary, mastery is hopeless. I suspect that one semester of college
1722 math can bring you up to speed. This book is my attempt to present this level of understanding.

1723 Chapter 2

1724 Number Systems: Stream 1

1725 This chapter is devoted to *Number Systems* (Stream 1), starting with the counting numbers \mathbb{N} . In this
1726 chapter we delve more deeply into the details of the topics of Lectures 4-9.

1727 2.1 Week 2

1728 In Section 2.1.1 we explore in more detail the two fundamental theorems of prime numbers, working
1729 out a sieve example, and explore the logarithmic integral $Li(N)$ which approximates the density of
1730 primes $\rho_k(N)$ up to prime N .

1731 The topics of Section 1.2.4 consider the practical details of computing the *greatest common divisor*
1732 (GCD) of two integers m, n (Matlab's routine `1=gcd(m,n)`), with detailed examples and comparing
1733 the algebraic and matrix methods. Homework assignments will deal with these two methods. Finally
1734 we discuss the relationship between coprimes and the GCD. In Section 1.2.5 we defined the Continued
1735 Fraction algorithm (CFA), a method for finding rational approximations to irrational numbers. **The**
1736 **CFA and GCD are closely related, but the relation needs to be properly explained.** In Section 1.2.7 we
1737 derive *Euclid's formula*, the solution for the Pythagorean triplets (PT), based on Diophantus's *chord/-*
1738 *tangent* method. This method is used many times throughout the course notes, first for computing
1739 Euclid's formula for the PTs, then for finding a related formula in Section 1.2.8 for the solutions to
1740 Pell's equation, and finally for finding the mapping from the complex plane to the extended complex
1741 plane (the Riemann sphere).

1742 Finally in Section 1.2.9 the general properties of the *Fibonacci sequence* is discussed. This equation
1743 is a special case of the second order digital resonator (well known in digital signal processing), so it
1744 has both historical and practical application for engineering. The general solution of the Fibonacci is
1745 found by taking the Z-transform and finding the roots, resulting in an eigenvalue expansion (Appendix
1746 D).

1747 2.1.1 Lec 4 Two theorems on primes

1748 Theorem 1: *Fundamental Theorem of Arithmetic*

Factoring integers: Every integer $n \in \mathbb{N}$ has a unique factorization (Stillwell, 2010, p. 43)

$$n = \prod_{k=1}^K \pi_k^{\beta_k}, \quad (2.1)$$

1749 where $k = 1, \dots, K$ indexes the integer's K prime factors π_k and their *multiplicity* β_k .

1750 **Examples:** $2312 = 2^3 \cdot 17^2 = \pi_1^3 \pi_7^2$ (i.e., $\pi_1 = 2, \beta_1 = 3; \pi_7 = 17, \beta_7 = 2$)
1751 $2313 = 3^2 \cdot 257 = \pi_3^2 \pi_{55}$ (i.e., $\pi_2 = 3, \beta_3 = 2; \pi_{55} = 257, \beta_{55} = 1$)

Integers 2312 and 2313 are said to be *coprime*, since they have no common factors. *Coprimes* may be identified via the *greatest common divisor*:

$$\gcd(a, b) = 1$$

1752 using the *Euclidean algorithm* (Stillwell, 2010, p. 41).

1753 **Theorem 2: Prime Number Theorem**

The primes are a random field since there is no way to predict when the next prime will occur. Thus one needs to use statistical methods to characterize their density. Based on a sample of approximately 3 million primes, Gauss showed empirically that the average total number of primes less than N is

$$\sum_{n=1}^N \delta_n \sim \frac{N}{\ln N}.$$

1754 These primes were obtained by manual calculations “as a pastime” in 1792-3 (Goldstein, 1973).

1755 Define $\delta_n = 1$ if n is a prime, and zero otherwise.¹.

It follows that the *average density of primes* is $\rho_\pi(N) \sim 1/\ln N$, thus

$$\rho_\pi(N) \equiv \frac{1}{N} \sum_{n=1}^N \delta_n \approx \frac{1}{N} Li(N) \equiv \frac{1}{N} \int_2^N \frac{d\xi}{\ln \xi},$$

1756 where $Li(N)$ is the *offset logarithmic integral* (Stillwell, 2010, p. 585). The primes are distributed
1757 as $1/\ln(n)$ since the average total number of primes is proportional to the *logarithmic integral* $Li(n)$
1758 (Goldstein, 1973; Fine, 2007).

1759 Here is a Matlab code that tests this formula:

```
1760 NP=1e6; % 10^6 primes
1761 p=primes(NP); %compute primes
1762 delta=zeros(1, NP); delta(p)=1; %put 1 at each prime
1763 rho=cumsum(delta)./cumsum(1:NP); %estimate of the density of primes
1764 figure(1)
1765 semilogy(rho); %plot of density vs number of primes
1766 figure(2)
1767 loglog(rho); %shows that 1/N drops mean too fast
1768 figure(3); loglog(cumsum(delta)./cumsum(1:NP)*0.44); %Power law normalization better
```

1769 Based on this script it seems that dividing by $1/N$ overcompensates for the growth of the $Li(N)$ function
1770 with N , and $N^{0.44}$ brings the growth to zero, for the case of a 10^6 primes. As the number grows to
1771 $N = \infty$, the optimal normalization is $1/N$.

1772 From the Prime Number Theorem it is clear that the density of primes is large (they are not scarce).
1773 As best I know there are no methods to find primes other than by the sieve method (Section ??, p. ??).
1774 If there is any good news it is that they only need to be computed once, and saved. In practical
1775 applications this doesn't help much given their large number. In theory, given primes π_n up to $n = N$,
1776 the density $\rho_\pi(N)$ could help one search for a particular prime of known size N , by estimating how
1777 many primes there are in the neighborhood of N .

1778 Not surprisingly, playing with primes has been a popular pastime of mathematicians. Perhaps this
1779 is because those who have made inroads, providing improved understanding, have become famous.

¹You may view δ_n for the first 100 numbers with the one-line Matlab/Octave command `stem(isprime(1:100))`

1780 **2.1.2 Lec 5 Greatest common divisor (GCD)**

1781 Multiplying two numbers together, or dividing one by the other, is very inexpensive on today's computer
 1782 hardware. However, factoring a large integer (i.e., 10^3 digits) into its primes, is very expensive. When
 1783 the integers are large, it is so costly that it cannot be done in a lifetime, even with the fastest computers.

1784 The obvious question is: "Can we find the largest common factor $k = \gcd(m, n)$ without factoring
 1785 (m, n) ?" The answer is "yes," with the *Euclidean algorithm* (EA). While the EA falls short of factoring,
 1786 it is fast and easily implemented.

1787 If the two integer are in factored form, the answer is trivial. For example $5 = \gcd(5 \cdot 13, 5 \cdot 17)$, and
 1788 $17 = \gcd(17 \cdot 53, 17 \cdot 3 \cdot 31)$. But what about $\gcd(901, 1581)$? So the problem that computing the GCD
 1789 solves is when the factors are not known. Since $901 = 53 \cdot 17$ and $1581 = 3 \cdot 17 \cdot 31$, $\gcd(901, 1581) = 17$,
 1790 which is not obvious.

1791 In Matlab the GCD may be computed using `k=gcd(m,n)`, which only allows integers as arguments
 1792 (and removes the sign).

Matrix method: The GCD may be written a matrix recursion, based on Eq. 2.1.2. The two starting numbers are given by the vector (m_0, n_0) . The recursion is then

$$\begin{bmatrix} m_{k+1} \\ n_{k+1} \end{bmatrix} = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} m_k \\ n_k \end{bmatrix}$$

1793 This recursion continues until $m_{k+1} < n_{k+1}$, at which point m and n must be swapped. Because the
 1794 output depends on the input, this is a nonlinear recursion (Postulate P1 (Linear/nonlinear) of Section
 1795 3.5.1, p. 102).

1796 The direct method is inefficient because in recursively subtract n many times until the resulting
 1797 m is less than n , as shown in Fig. 2.1. It also must test for $m < n$ at each iteration, and then swap
 1798 m and n once that condition is met. This recursion is repeated until $m_{k+1} = 0$. At that stage the
 1799 GCD is n_{k+1} . Figure 2.1, along with the above matrix relation, give the best insight into the Euclidean
 1800 Algorithm, but at the cost of low efficiency.

1801 Below is a Matlab code to find the gcd based on the strict definition of the EA:

```
1802 n = gcd(m,n)
1803 while m ~=0
1804     A=m; B=n;
1805     m=max(A,B); n=min(A,B); %m>n
1806     m=m-n;
1807 end
```

1808 This program keeps looping until $m = 0$. It first finds the min and max of the inputs, sets m as the
 1809 max and n as the minimum. The next line $m = m - n$ removes the smaller number from the larger
 1810 one. It then loops back and repeats the cycle. Thus the EA is a two step recursive method.

Division with rounding method: This method implements Eq. 2.2. It is not necessary to test that $m_{k+1} < n_{k+1}$. After computing the new value of n , using the floor function, the old value of m is saved as the new value of n (thus $m_{k+1} > n_{k+1}$)

$$\begin{bmatrix} m_{k+1} \\ n_{k+1} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 & -\lfloor \frac{m}{n} \rfloor \end{bmatrix} \begin{bmatrix} m_k \\ n_k \end{bmatrix}. \quad (2.2)$$

1811 where $\lfloor x \rfloor$ finds the integer part of x ($\lfloor x \rfloor$ rounds toward $-\infty$). The method terminates when $m_{k+1} = 0$.
 1812 The previous values m_k, n_k are the solutions to Bézout's identity ($\gcd(n, m)=1$, namely $m_k m_0 + n_k n_0 =$
 1813 1), since the terminal state and the GCD of a, b is $m - n \lfloor m/n \rfloor = 0$, for which $n = \gcd(a, b)$.

1814 Below is 1-line vectorized code that is much more efficient than the direct matrix method:

```

1815 k = gcd(m,n) %entry point: input m,n; output k=gcd(m,n)
1816 M=[abs(m),abs(n)]; %init M
1817 while M(2) ~=0 % < n*eps to ‘almost work’ with irrational inputs
1818     M = [M(2) - M(1)*floor(M(2)/M(1)); M(1)]; %M = [M(1); M(2)] with M(1)<M(2)
1819 end

```

1820 With a minor extension in the test for “end,” this code can be made to work with irrational inputs:
 1821 e.g.: $(n\pi, m\pi)$.

1822 This method calculates the number of times $n < m$ must subtract from m using the floor function.
 1823 Note that the new value of m ($M(1)$) is always less than n ($M(2)$), and must remain greater or equal
 1824 to zero. This one-line vector operation is then repeated until the remainder ($M(1)$) is 0. The gcd is
 1825 then n ($M(2)$). When using irrational numbers, this still works except the error is never exactly zero,
 1826 due to IEEE 754 rounding. Thus the criterion must be that the error is within some small factor times
 1827 the smallest number (which in Matlab is the number $\text{eps} = 2.220446049250313 \times 10^{-16}$).

1828 Thus without factoring the two numbers, the Euclidean algorithm recursively finds the gcd simply
 1829 by ordering the two numbers and then updating them. Perhaps this is best seen with some examples.

1830 The GCD is an important and venerable method, useful in engineering and mathematics, but, as
 1831 best I know, is not typically taught in the traditional engineering curriculum.

1832 **Graphical meaning of the GCD:** The Euclidean algorithm is actually very simple when viewed
 1833 graphically. In Fig. 2.1 we show what is happening as one approaches the threshold. After reaching
 1834 the threshold, the two number must be swapped, which is addressed by upper row of Eq. 2.2.

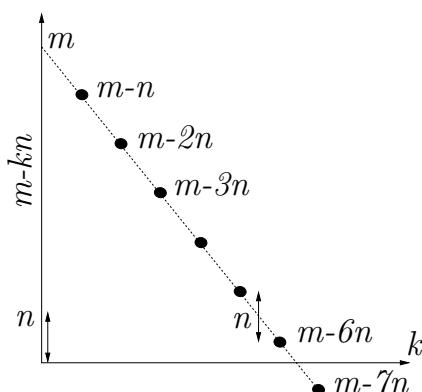

Figure 2.1: The Euclidean Algorithm recursively subtracts n from m until the remainder $m - kn$ is either less than n or zero. For the case depicted here the value of k that renders the remainder less than n is $k = 6$. If one more step were taken ($k = 7$) the remainder becomes negative. By linear interpolation we can find that $m - an = 0$ when $a = m/n$, which for this example is close to $a=6.5$. In this example $6 = \text{floor}(m/n) < n$.

Multiplication is simply recursive addition, and finding the gcd takes advantage of this fact. Lets take a trivial example, $(9,6)$. Taking the difference of the larger from the smaller, and writing multiplication as sums, helps one see what is going on. Since $6=3*2$, this difference may be written two different ways

$$9 - 6 = (3 + 3 + 3) - (3 + 3) = 0 + 0 + 3 = 3,$$

or

$$9 - 6 = (3 + 3 + 3) - (2 + 2 + 2) = 1 + 1 + 1 = 3.$$

1835 Written out the first way, it is 3, because subtracting $(3+3)$ from $(3+3+3)$ leaves 3. Written out
 1836 in the second way, each 3 is matched with a -2, leaving 3 ones, which add to 3. Of course the two
 1837 decompositions must yield the same result because $2 \cdot 3 = 3 \cdot 2$. Thus finding the remainder of the
 1838 larger number minus the smaller yields the gcd of the two numbers.

1839 **Coprimes:** When the gcd of two integers is 1, the only common factor is 1. This is of key importance
 1840 when trying to find common factors between the two integers. When $1 = \text{gcd}(m, n)$ they are said to be
 1841 *coprime*, which can be written as $m \perp n$. By definition, the largest common factor of coprimes is 1.
 1842 But since 1 is not a prime ($\pi_1 = 2$), they have no common primes.

1843 **Generalizations of GCD:** The GCD may be generalized in several significant ways. For example
 1844 what is the GCD of two polynomials? To answer this question one must factor the two polynomials to
 1845 identify common roots. This will be discussed in more detail in Section 3.2.2.

1846 2.1.3 Lec 6 Continued Fraction Expansion (CFA)

1847 **Continued Fractions and circuit theory:** One of the most powerful generalizations of the CFA
 1848 seems to be the expansion of a function of a complex variable, such as the expansion of an impedance
 1849 $Z(s)$, as a function of complex frequency s . This idea is described in Fig. 2.2 and Eq. 2.3. This
 1850 is especially interesting in that it leads to a physical interpretation of the impedance in terms of a
 1851 transmission line (horn), a structure well known in acoustics having a variable area $A(x)$ as function of
 1852 the range variable x .

1853 The CFA expansion is of great importance in circuit theory, where it is equivalent to an infinitely
 1854 long segment of transmission line, composed of series and shunt impedance elements. Thus such a
 1855 cascade network composed of 1 ohm resistors, has an input impedance of $(1 + \sqrt{5})/2 \approx 1.6180$ [ohms].

The CFA may be extended to monomials in s . For example consider the input impedance of a
 cascade L-C transmission line as shown in Fig. 2.2. The input impedance of this transmission line is
 given by a continued fraction expansion of the form

$$Z_{in} = sL + \frac{1}{sC + \frac{1}{sL + \frac{1}{sC + \frac{1}{\dots}}}} \quad =: [sL; sC, sL, sC, \dots]. \quad (2.3)$$

1856 where we have again used the bracket notation to describe the CFA coefficients.

In some ways, Eq. 2.3 is reminiscent of the Taylor series expansion about $s = 0$, yet very different.
 In the limit, as the frequency goes to zero ($s \rightarrow 0$), the impedance of the inductors go to zero, and that
 of the capacitors go to ∞ . In physical terms, the inductors become short circuits, while the capacitors
 become open circuits. The precise relation may be quantified by the use of composition, described in
 Fig. 1.11 of Section 2.1.3 (p. 53). Specifically

$$\begin{bmatrix} P_1 \\ U_1 \end{bmatrix} = \begin{bmatrix} 1 & sL \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ sC & 1 \end{bmatrix} \dots \begin{bmatrix} 1 & sL \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ sC & 1 \end{bmatrix} \begin{bmatrix} 1 & sL \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ sC & 1 \end{bmatrix} \begin{bmatrix} P_2 \\ -U_2 \end{bmatrix}. \quad (2.4)$$

1857 It seems possible that this is the CFA generalization of the Taylor series expansion, built on composition.
 1858 If we were to do the algebra we would find that $A(s), B(s), C(s), D(s)$ (i.e., Sections 1.3.6, 3.3.2)
 1859 are ratios of polynomials having rational expansions as Taylor series. This seems like an important
 1860 observation, that should have support beyond that of the engineering literature (Campbell, 1903;
 1861 Brillouin, 1953; Ramo et al., 1965). Its interesting that (Brillouin, 1953) credits (Campbell, 1903).

In terms of the TL, it is a long piece of wire, with a delay determined by the velocity and the length,
 in units of cells each of length Δ . There are two basic parameters that characterize a transmission line,
 the characteristic resistance $r_0 = \sqrt{Z/Y}$ and the wave number

$$\kappa = 1/\sqrt{ZY} = s/\sqrt{LC} = s/c,$$

which gives $c = \sqrt{LC}$. Each of these is a constant as $\Delta \rightarrow 0$, and in that limit the waves travel as

$$f(t - x/c) = e^{-\kappa x} e^{-st},$$

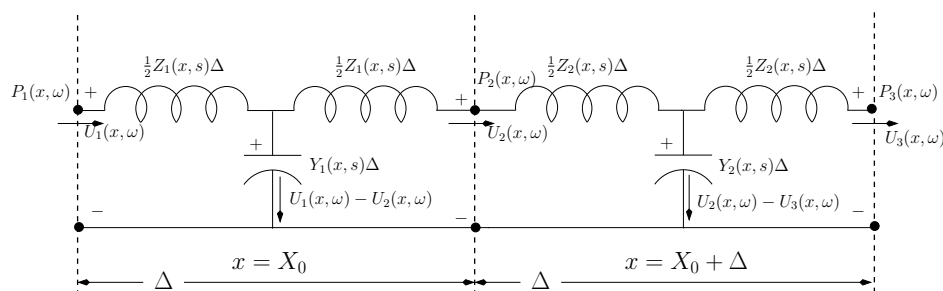

Figure 2.2: This transmission line (TL) is known as a low-pass filter wave-filter (Campbell, 1922), composed of series inductors having an impedance $Z_k = sL$ and shunt admittance $Y_k = sC$. The characteristic resistance of the TL is $r_0 = \sqrt{Z_k/Y_k}$ and the wave velocity is $\kappa = \sqrt{Z_k Y_k} = s/\sqrt{LC} = s/c$. Thus the wave velocity is $c = 1/\sqrt{LC}$. The length Δ [m] defines the physical size of each cell. For long wavelengths the wave-filter acts as a pure delay. But when the frequency increases above a cutoff frequency $f_c > c/\Delta$, the wavelength $\lambda = c/f$ is less than the size of a section Δ , and the system response becomes very high-order low-pass filter.

1862 with a wave resistance ($r_0 = \sqrt{L/C}$). The total delay $T = L/c$ where Δ is the TL cell length in meters
 1863 and c is the velocity $c = 1/\sqrt{LC}$ in meters/second.

1864 Since the CFA has a physical representation as a transmission line, as shown in Fig. 2.2, it can be
 1865 of high utility for the engineer.² The theory behind this will be discussed in greater detail in Chapter
 1866 5. If you're ready to jump ahead, read the interesting book by Brillouin (1953) and the collected works
 1867 of Campbell (1937).

1868 2.2 Week 3

1869 2.2.1 Lec 7 Pythagorean triplets (PTs) and Euclid's formula ,

1870 Pythagorean triplets (PTs) have many applications in architecture and scheduling, which explains why
 1871 they are important and heavily studied. For example, if one wished to construct a triangle with a
 1872 perfect 90° angle, then the materials need to be squared off as shown in Fig. 1.8. The lengths of the
 1873 sides need to satisfy PTs.

1874 **Derivation of Euclid's formula:** The problem is to find integer solutions to the Pythagorean
 1875 theorem (Eq. 1.1, p. 15). The solution method, said to be due to Diophantus, is call a *chord/tangent*
 1876 method (Stillwell, 2010, p. 48). The method composes (Section 3.2.3) a line and a circle, where the
 1877 line defines a chord within the circle (its not clear where the tangent line might go). The slope of the
 1878 line is then taken to be rational, allowing one to determine integer solutions of the intersections points.
 1879 This solution for *Pythagorean triplets* $[a, b, c]$ is known as *Euclid's formula* (Eq. 1.3, p. 1.3 (Stillwell,
 1880 2010, p. 4–9, 222).

1881 The derivation methods of Diophantus have been lost, but Fermat and Newton figured out what
 1882 Diophantus must have done (Stillwell, 2010, p. 49). Since Diophantus worked before algebra was
 1883 invented, he described all the equations in prose (Stillwell, 2010, p. 93).

1884 **Derivation of Euclid's formula:** The derivation is outlined in Fig. 2.3. Starting from two integers
 1885 $[p > q > 0] \in \mathbb{N}$, composing a line having a rational slope $t = p/q$, with a circle (Stillwell, 2010, p. 6),
 1886 reveals the formula for the Pythagorean triplets.

1887 The construction starts with a circle and a line, which is terminated at the point $(-1, 0)$. The slope
 1888 of the line is the free parameter t . By composing the circle and the line (i.e., solving for the intersection
 1889 of the circle and line), the formula for the intersection point (a, b) may be determined in terms of t ,
 1890 which will then be taken as the rational slope $t = p/q \in \mathbb{Q}$.

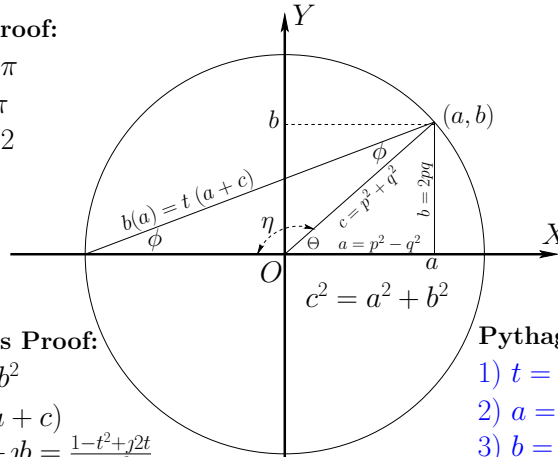

²Continued fraction expansions of functions are know in the circuit theory literature as a *Cauer* synthesis (Van Valkenburg, 1964b).

Euclid's formula for Pythagorean triplets $[a, b, c]$

5.2.4

Euclidean Proof:

- 1) $2\phi + \eta = \pi$
- 2) $\eta + \Theta = \pi$
- 3) $\therefore \phi = \Theta/2$

Diophantus's Proof:

- 1) $c^2 = a^2 + b^2$
- 2) $b(a) = t(a + c)$
- 3) $\zeta(t) \equiv a + jb = \frac{1-t^2+j2t}{1+t^2}$
- 4) $\zeta = |c|e^{i\theta} = |c|\frac{1+it}{1-it} = |c|(\cos(\theta) + i \sin(\theta))$

Pythagorean triplets:

- 1) $t = p/q \in \mathbb{Q}$
- 2) $a = p^2 - q^2$
- 3) $b = 2pq$
- 4) $c = p^2 + q^2$

Figure 2.3: Derivation of Euclid's formula for the Pythagorean triplets $[a, b, c]$, based on a composition of a line, having a rational slope $t = p/q \in \mathbb{Q}$, and a circle $c^2 = a^2 + b^2$, $[a, b, c] \in \mathbb{N}$. This analysis is attributed to Diophantus (250 CE), and today such equations are called Diophantine equations. PTs have applications in architecture and scheduling, and many other practical problems.

1891 In Fig. 2.3 there are three panels, two labeled "Proofs." The *Euclidean Proof* shows the angle
 1892 relationships of two triangles, the first an isosceles triangle formed by the chord, having slope t and
 1893 two equal sides formed from the radius of the circle, and a second right triangle having its hypotenuse
 1894 as the radius of the circle and its right angle vertex at $(a, 0)$. As shown, it is this smaller right triangle
 1895 that must satisfy Eq. 1.1. The inner right triangle has its hypotenuse c between the origin of the circle
 1896 (O) to the point (a, b) . Side a forms the x axis and side b forms the y ordinate. Thus by construction
 1897 Eq. 1.1 must be obeyed.

1898 The *Diophantus Proof* is the heart of Diophantus' (250 CE) derivation, obtained by composing a
 1899 line and a circle, as shown in Fig. 2.3. Diophantus's approach was to fix the line at $x = -c$ having a
 1900 rational slope $t = p/q \in \mathbb{Q}$. He then solved for the intersection of the line and the circle, at (a, b) .

The formula for the line is $b(a) = t(a + c)$, which goes through the points $(-c, 0)$ and (a, b) . The circle is given by $a^2 + b^2 = c^2$. Composing the line with the circle gives

$$\begin{aligned}
 a^2 + (t(a + c))^2 &= c^2 \\
 a^2 + t^2(a^2 + 2ac + c^2) &= c^2 \\
 (1 + t^2)a^2 + 2ct^2a + c^2(t^2 - 1) &= 0
 \end{aligned}$$

1901 This last equation is a quadratic equation in a . In some sense it is not really a quadratic equation,
 1902 since we know that $a = -c$ is a root.

Solving for $a(t)$ is best done by completing the square. Dividing by $1 + t^2$

$$a^2 + \frac{2ct^2}{1 + t^2}a + \frac{c^2(t^2 - 1)}{1 + t^2} = 0,$$

makes it easy to complete the square, and thus find the roots:

$$\begin{aligned} \left(a + \frac{ct^2}{1+t^2}\right)^2 - \left(\frac{ct^2}{1+t^2}\right)^2 + \frac{c^2(t^2-1)}{1+t^2} &= 0 \\ \left(a + \frac{ct^2}{1+t^2}\right)^2 - \frac{c^2t^4}{(1+t^2)^2} + \frac{c^2(t^2-1)(t^2+1)}{(1+t^2)^2} &= 0 \\ \left(a + \frac{ct^2}{1+t^2}\right)^2 - \frac{c^2t^4 + c^2(t^2-1)}{(1+t^2)^2} &= 0 \\ \left(a + \frac{ct^2}{1+t^2}\right)^2 &= \left(\frac{c}{1+t^2}\right)^2 \end{aligned}$$

1903 The second to last equation simplifies (magic happens) because the known root $a = -c$ is embedded
1904 in the result.

Taking the square root gives the two roots

$$\begin{aligned} a_{\pm} + \frac{ct^2}{1+t^2} &= \pm \frac{c}{1+t^2} \\ (1+t^2)a_{\pm} &= -ct^2 \pm c = -c(t^2 \mp 1) \\ a_{\pm} &= -c \frac{t^2 \mp 1}{1+t^2}. \end{aligned}$$

1905 The known root is $a_+ = -c$, because when the sign is +, the numerator and denominator terms cancel.
The root we have been looking for is a_-

$$a_- = c \frac{1-t^2}{1+t^2},$$

which allows us to solve for b_-

$$\begin{aligned} b_- &= \pm \sqrt{c^2 - a_-^2} \\ &= \pm c \sqrt{1 - \left(\frac{1-t^2}{1+t^2}\right)^2} \\ &= \pm c \sqrt{\frac{(1+t^2)^2 - (1-t^2)^2}{(1+t^2)^2}} \\ &= \pm \frac{2ct}{t^2+1}. \end{aligned}$$

Therefore the coordinates (a, b) , the intersection point of the line and circle, are

$$(a(t), b(t)) = c \frac{[1-t^2, 2t]}{1+t^2}.$$

1906 To obtain the Pythagorean triplets, as given in Fig. 2.3 and Eq. 1.3 of Section 1.2.7 (p. 37), set
1907 $t = p/q$, assuming $p > q \in \mathbb{Z}$, and simplify.

Complex roots: Defining the root as a complex number $\zeta(\Theta) \equiv a + bj$ forces $a \perp b$ (i.e., forces the right triangle) and gives us polar coordinates, as defined by the figure as the Euclidean Proof

$$\zeta(\Theta) = |c|e^{\Theta j} = |c|(\cos(\Theta) + j \sin(\Theta)).$$

This naturally follows since

$$\zeta = |c|e^{j\Theta(t)} = |c|\frac{1-t^2+2tj}{1+t^2} = |c|\frac{(1+jt)(1+jt)}{(1+tj)(1-tj)} = (q+pj)\sqrt{\frac{q+jp}{q-pj}}.$$

1908 Examples of PTs include $a = 2^2 - 1^2 = 3$, $b = 2 \cdot 2 \cdot 1 = 4$, and $c = 2^2 + 1^2 = 5$, $3^2 + 4^3 = 5^2$.

1909 Defining $p = q + N$ ($N \in \mathbb{N}$) gives slightly better parametric representation of the answers, as the
 1910 pair (q, N) are a more systematic representation than (p, q) , because the condition $p > q$ is accounted
 1911 for, so the general properties of the solutions are expressed more naturally. Note that $b+c$ must always
 1912 be a perfect square since $b+c = (p+q)^2 = (2q+N)^2$, as first summarized by Fermat Stillwell (2010,
 1913 p. 212).

1914 s

1915 2.2.2 Lec 8 Pell's Equation

1916 **Eigenvalue solution to Pell's equation:** To provide a full understanding of what was known to
 1917 the Pythagoreans, it is helpful to provide the full solution to this recursive matrix equation, based on
 1918 what we know today.

1919 As shown in Fig. 1.10, (x_n, y_n) may be written as a power series of the 2x2 matrix A . To find the
 1920 powers of a matrix, the well know modern approach is to *diagonalize* the matrix. For the 2x2 matrix
 1921 case, this is relatively simple. The final result written out in detail for the general solution (x_n, y_n) , as
 1922 detailed in Appendix D (p. 137):

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} = j^n \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix}^n \begin{bmatrix} 1 \\ 0 \end{bmatrix} = E \begin{bmatrix} \lambda_+^n & 0 \\ 0 & \lambda_-^n \end{bmatrix} E^{-1} \begin{bmatrix} 1 \\ 0 \end{bmatrix}. \tag{2.5}$$

The eigen-values are $\lambda_{\pm} = j(1 \pm \sqrt{2})$ while the eigen-matrix and its inverse are

$$E = \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 0.8165 & 0.8165 \\ 0.5774 & -0.5774 \end{bmatrix}, \quad E^{-1} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ 1 & -\sqrt{2} \end{bmatrix} = \begin{bmatrix} 0.6124 & 0.866 \\ 0.6124 & -0.866 \end{bmatrix}$$

The relative “weights” on the two eigen-solutions are equal, as determined by

$$E^{-1} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ 1 & -\sqrt{2} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 \\ 1 \end{bmatrix}.$$

We still need to prove that

$$\frac{x_n}{y_n} \xrightarrow{\infty} \sqrt{N},$$

1923 which follows intuitively from Pell's equation, since as $(x_n, y_n) \rightarrow \infty$, the difference between x^2 and
 1924 $2y^2$, the (± 1) becomes negligible.

1925 WEEK 4

1926

1927 2.3 Week 4

1928 2.3.1 Lec 9 Fibonacci Numbers

1929 The Fibonacci sequence is famous in number theory. It is said that the sequence commonly appears in
 1930 physical systems. Fibonacci numbers are related to the “golden ratio” $(1 + \sqrt{5})/2$, which could explain
 1931 why these numbers appear in nature.

But from a mathematical point of view, the Fibonacci sequence does not seem special. It is generated by a linear recursion relationship, where the next number is the sum of the previous two (Eq. 1.6, p. 40)

$$x_{n+1} = x_n + x_{n-1}. \quad (2.6)$$

1932 The term *linear* means that the principle of superposition holds (P1 (linear/nonlinear) of Section
1933 3.5.1). To understand the meaning of this we need to explore the z-transform, the discrete-time version
1934 of the Laplace transform. We will return to this in Chapter 4.

A related linear recurrence relation is that the next output be the average of the previous two

$$x_{n+1} = \frac{x_n + x_{n-1}}{2}.$$

1935 In some ways this relationship is more useful than the Fibonacci recursion, since it perfectly removes
1936 oscillations of the form -1^n (it is a 2-sample *moving average*, a trivial form of low-pass filter). And it
1937 is stable, unlike the Fibonacci sequence, with stable real eigenvalues (digital-poles) at $\lambda_{\pm} = (1, -0.5)$.
1938 Perhaps biology prefers unstable poles (to propagate growth?).

The most general 2d order recurrence relationships (i.e., digital filter) is

$$x_{n+1} = -bx_n - cx_{n-1},$$

1939 with filter constants $b, c \in \mathbb{R}$ and poles at (completing the square), $\lambda_{\pm} = -b/2 \pm \sqrt{c - b^2/2}$.

Equation 2.6 may be written as a 2x2 matrix relationship. If we define $y_{n+1} = x_n$ then Eq. 2.6 is equivalent to (Eq. 1.7, p. 40)

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix}. \quad (2.7)$$

1940 The first equation is $x_{n+1} = x_n + y_n$ while the second is $y_{n+1} = x_n$, which is the same as $y_n = x_{n-1}$.
1941 Note that the Pell 2x2 recursion is similar in form to the Fibonacci recursion. This removes mystique
1942 from both equations.

General properties of the Fibonacci numbers^a

$$x_n = x_{n-1} + x_{n-2}$$

- This is a 2-sample *moving average* difference equation with an unstable pole
- $x_n = [0, 1, 1, 2, 3, 5, 8, 13, 21, 34, \dots]$, assuming $x_0 = 0, x_1 = 1$:
- Analytic solution (Stillwell, 2010, p. 194): $\sqrt{5} x_n \equiv \left(\frac{1+\sqrt{5}}{2}\right)^n - \left(\frac{1-\sqrt{5}}{2}\right)^n \rightarrow \left(\frac{1+\sqrt{5}}{2}\right)^\infty$
 - $\lim_{n \rightarrow \infty} \frac{x_{n+1}}{x_n} = \frac{1+\sqrt{5}}{2}$
 - Example: $34/21 = 1.6190 \approx \frac{1+\sqrt{5}}{2} = 1.6180$ **0.10% error**
- Matlab's `rat(1 + sqrt(5)) = 3 + 1/(4 + 1/(4 + 1/(4 + 1/(4)))) =: [3; 4, 4, 4, ...]`

^ahttps://en.wikipedia.org/wiki/Fibonacci_number

Figure 2.4: Properties of the Fibonacci numbers (Stillwell, 2010, p. 28).

1943 In the matrix diagonalization of the Pell equation we found that the eigenvalues were $\lambda_{\pm} = 1 \mp \sqrt{N}$,
1944 and the two solutions turned out to be powers of the eigenvalues. The solution to the Fibonacci recursion
1945 may similarly be expressed in terms of a matrix. These two cases may thus be reduced by the same
1946 2x2 eigenvalue solution method.

The eigenvalues of the Fibonacci matrix are

$$\det \begin{bmatrix} 1 - \lambda & 1 \\ 1 & -\lambda \end{bmatrix} = \lambda^2 - \lambda - 1 = (\lambda - 1/2)^2 - (1/2)^2 - 1 = (\lambda - 1/2)^2 - 5/4 = 0$$

1947 thus $\lambda_{\pm} = \frac{1 \pm \sqrt{5}}{2} = [1.618, -0.618]$.

1949 Chapter 3

1950 Algebraic Equations: Stream 2

1951 3.1 Week 4

1952 3.1.1 Lec 11 Algebra and geometry as physics

Before Newton could work out his basic theories, algebra needed to be merged with Euclid's early quantification of geometry. The key to putting geometry and algebra together is the Pythagorean theorem (Eq. 1.1), which is both geometry and algebra. To make the identification with geometry the sides of the triangle needed to be viewed as a length. This is done by recognizing that the area of a square is the square of a length. Thus a geometric proof requires one to show that the area of the square $A = a^2$ plus the area of square $B = b^2$ must equal the area of square $C = c^2$. There are many such constructions that show $A + B = C$ for the right triangle. It follows that in terms of coordinates of each vertex, the length of c is given by

$$c = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}, \quad (3.1)$$

1953 with $a = x_2 - x_1$ and $b = y_2 - y_1$. Thus Eq. 1.1 is both an algebraic and a geometrical statement. This
1954 is not immediately obvious.

1955 Analytic geometry is based on coordinates of points, with the length given by Eq. 3.1. Geometry
1956 treats lines as lengths without specifying the coordinates (Eq. 1.1). Algebra gave a totally new view
1957 to the quantification of geometrical lengths by introducing a coordinate system. This resulted in an
1958 entire new way to work with conic sections, which were now explained in terms of equations having
1959 coordinate systems. When viewed through the lens of algebra, Eq. 1.1 is a circle having radius c .
1960 Complex numbers provide an equivalent representations, since if $z = x + yj$, the unit circle is $z = e^{j\theta}$
1961 and $|z|^2 = x^2 + y^2$. Here we explore the relationships between points, represented as coordinates,
1962 describing geometrical objects. We shall do this with simple examples from analytic geometry.

1963 For example, in terms of the geometry, the intersection of two circles can occur at two points, and
1964 the intersection of two spheres gives a circle. These ideas may be verified using algebra, but in a very
1965 different, since the line can traverse through the circle, like a piece of thread going through the eye of
1966 a needle. In such cases the intersections are complex intersections.

1967 For each of these problems, the lines and circles may intersect, or not, depending on how they are
1968 drawn. Yet we now know that even when they do not intersect on the sheet of paper, they still have
1969 an intersection, but the solution is $\in \mathbb{C}$. Finding such solutions require the use of algebra rather than
1970 geometry. These ideas were in the process of being understood, first by Fermat and Descartes, then by
1971 Newton, followed by the Bernoulli family and Euler.

1972 **Complex analytic functions:** A very delicate point, that seems to have been ignored for centuries,
1973 is that the roots of $P_n(x)$ are, in general, complex, namely $x_k \in \mathbb{C}$. It seems a mystery that complex
1974 numbers were not accepted once the quadratic equation was discovered, but they were not. Newton
1975 called complex roots *imaginary*, presumably in a pejorative sense. The algebra of complex numbers

1976 is first attributed to Bombelli in 1575, more than 100 years before Newton. One can only begin to
 1977 imagine what Bombelli learned from Diophantus, following his discovery of Diophantus' Arithmetic,
 1978 that he discovered in the Vatican library (Stillwell, 2010, p. 51).

1979 It is interesting that Newton was using power series with fractional degree, thus requiring multi-
 1980 valued solutions, much later to be known as *branch cuts* (c1851). These topics will be explored in
 1981 Section 3.1.1.

When the argument is complex, analytic functions takes on an entirely new character. For example Euler's identity (1748) with $z = x + yj \in \mathbb{C}$ results in $e^z \in \mathbb{C}$ (Stillwell, 2010, p. 315)

$$e^z = e^x(\cos(y) + j \sin(y)).$$

1982 It should be clear that the complex analytic functions results in a new category of algebra, with no
 1983 further assumptions beyond allowing the argument to be complex.

1984 Prior to 1851 most of the analysis *assumed* that the roots of polynomials were real ($x_k \in \mathbb{R}$),
 1985 even though there was massive evidence that they were complex ($x_n \in \mathbb{C}$). This is clearly evident in
 1986 Newton's work (c1687): When he found a non-real root, he ignore it (Stillwell, 2010, pp. 115-7). Euler
 1987 (c1748) first derived the Zeta function as a function of real arguments $\zeta(x)$ with $\zeta, x \in \mathbb{R}$. Cauchy
 1988 (c1814) broke this staid thinking with his analysis of complex analytic functions, but it was Riemann
 1989 thesis (c1851), when working with Gauss (1777-1855), which had a several landmark breakthroughs.
 1990 In this work Riemann introduced the *extended complex plane*, which explained the *point* at infinity. He
 1991 also introduced *Riemann sheets* and *Branch cuts*, which finally allowed mathematics to better describe
 1992 the physical world (Section 1.4.2).

1993 Once the argument of an analytic function is complex, for example an impedance $Z(s)$, or the Rie-
 1994 mann Zeta function $\zeta(s)$, The development of complex analytic functions led to many new fundamental
 1995 theorems. Complex analytic functions have poles and zeros, branch cuts, Riemann sheets and can be
 1996 analytic at the point at infinity. Many of these properties were first worked out by Augustin-Louis
 1997 Cauchy (1789-1857), who drew heavily on the much earlier work of Euler, expanding Euler's ideas into
 1998 the complex plane (Chapter 4).

1999 Systems of equations

We don't need to restrict ourselves to polynomials in one variable. In some sense $y(x) = ax + b$ is already an equation in two variables. Moving beyond such a simple example, we can work with the equation for a circle, having radius r

$$y^2 + x^2 = r^2,$$

2000 which is quadratic in two variables. Solving for roots $y(x_r) = 0$ ($y^2(x_r) = r^2 - x_r^2 = 0$) gives $(r -$
 2001 $x_r)(r + x_r)$, which simply says that when the circle crosses the $y = 0$ line at $x_r = \pm r$.

This equation may also be factored as

$$(y - xj)(y + xj) = r^2,$$

2002 as is easily demonstrated by multiplying out the two monomials. This does not mean that a circle has
 2003 complex roots. A root is defined by either $y(x_r) = 0$ or $x(y_r) = 0$.

Writing the conic as a 2d degree polynomial gives

$$P_2(x) = ax^2 + bx + c,$$

with $y^2(x) = -P_2(x)$. Setting this equal to zero and completing the square (Eq. 1.12, p. 43), gives the equation for the roots

$$\left(x_{\pm} + \frac{b}{2a}\right)^2 - \left(\frac{b}{2a}\right)^2 + \frac{c}{a} = 0,$$

or

$$x_{\pm} = -\frac{b}{2a} \pm \sqrt{\left(\frac{b}{2a}\right)^2 - \frac{c}{a}}.$$

The polynomial in factored form is

$$y^2 = -\left(x - \frac{b}{2a}\right)^2 + \left(\frac{b}{2a}\right)^2 - \frac{c}{a},$$

is a conic section, and becomes a circle with $a = 1$, $b = 0$ and $c = -r^2$.

3.2 Week 5

3.2.1 Lec 12 The physics behind complex analytic expressions: linear vs. nonlinear

The question we address here is “When do multi-variable complex analytic expressions appear in physics?” The most common example comes from the solution of the wave equation (Eq. 1.8) in three dimensions. Such cases arise in wave-guide problems, semiconductors, plasma waves, or for acoustic wave propagation in crystals (Brillouin, 1960) and the earth’s mantle (e.g., seismic waves, earthquakes, etc.). The solutions to these problems are based on the *eigenfunction* for the *vector wave equation* (see Chapter 5),

$$P(s, \mathbf{x}) = e^{st} e^{-\boldsymbol{\kappa} \cdot \mathbf{x}}, \quad (3.2)$$

where $\mathbf{x} = [x\hat{x} + y\hat{y} + z\hat{z}]$ is a vector pointing in the direction of the wave, $[\hat{x}, \hat{y}, \hat{z}]$ are unit vectors in the three dimensions and $s = \sigma + \omega j$ [rad] is the Laplace frequency. The function $\boldsymbol{\kappa}(s)$ is the complex vector *wave number*, which describes the propagation of a plane wave of radian frequency ω , in the \mathbf{x} direction.

Just as the frequency $s = \sigma + \omega j$ must be complex, it is important to allow the *wave number* function¹ to be complex,² because in general it will have a real part, to account for losses as the wave propagates. While it is common to assume there are no losses, in reality this assumption cannot be correct. In many cases it is an excellent approximation (e.g., even the losses of light in-vacuo are not zero) that gives realistic answers. But it is important to start with a notation that accounts for the most general situation, so that when losses must be accounted for, the notation need not change. With this in mind, we take the vector wave number to be complex

$$\boldsymbol{\kappa} = \mathbf{k}_r + \mathbf{k}_j,$$

where vector expression for the *lattice vector* is the imaginary part of $\boldsymbol{\kappa}$

$$\Im \boldsymbol{\kappa} = \mathbf{k} = \frac{2\pi}{\lambda_x} \hat{x} + \frac{2\pi}{\lambda_y} \hat{y} + \frac{2\pi}{\lambda_z} \hat{z}, \quad (3.3)$$

is the vector wave number for three dimensional solutions.

Equation Eq. 3.2 is linear in \mathbf{x} . If one takes the derivative with respect to either time or space,

$$\frac{\partial}{\partial t} e^{st} e^{-\boldsymbol{\kappa} \cdot \mathbf{x}} = s e^{st} e^{-\boldsymbol{\kappa} \cdot \mathbf{x}}, \quad \frac{\partial}{\partial x} e^{st} e^{-\boldsymbol{\kappa} \cdot \mathbf{x}} = \frac{2\pi}{\lambda_x} e^{st} e^{-\boldsymbol{\kappa} \cdot \mathbf{x}},$$

we find the eigenvalue of that derivative.

The units of $\boldsymbol{\kappa}$ are reciprocal length [m^{-1}] since $\boldsymbol{\kappa} \cdot \mathbf{x}$ has units of radians. When there are losses $\kappa_r(s) = \Re \boldsymbol{\kappa}(s)$ must be a function of frequency, due to the physics behind these losses. In many important cases, such as loss-less wave propagation in semiconductors, $\boldsymbol{\kappa}(\mathbf{x})$ is a function of direction and position (Brillouin, 1960).

When the eigenfunction Eq. 3.2 is applied to the wave equation, a quadratic (degree 2) algebraic expression results, known as the *dispersion relation*. The three dimensional dispersion relation

$$\left(\frac{s}{c}\right)^2 = \boldsymbol{\kappa} \cdot \boldsymbol{\kappa} \quad (3.4)$$

¹This function has many names in the literature, all of which are confusing. It is called the *wave number*, *propagation constant* and the Brillouin zone *dispersion function* (Brillouin, 1953, Ch. 1). However, its neither a number nor constant.

²In fact $\boldsymbol{\kappa}(s)$ is a complex analytic function of the Laplace frequency s .

is a complex analytic algebraic relationship in four variables, frequency s and the three complex *lattice wave numbers*. This represents a three-dimensional generalization of the well know relation between wavelength and frequency $f\lambda = c$. For plane waves propagating in free space, assuming no loss, $|\kappa(s)| = \pm|s/c|$, where the sign accounts for the direction of the plane wave.

This scalar relation ($f\lambda = c$) was first deduced by Galileo in the 16th century and was then explored further by Mersenne a few years later.³ This relationship would have been important to Newton when formulating the wave equation, which he needed to estimate the speed of sound. We shall return to this in Chapters 4 and 5.

Hilbert space: Another important example of algebraic expressions in mathematics is Hilbert's generalization of Eq. 1.1, known as the Schwartz inequality, shown in Fig. 3.2. What is special about this generalization is that it proves that when the vertex is 90° , the length of the leg is minimum.

Geometry: Hilbert space: [David Hilbert 1900](#)

- Define:

1. Vectors $U, V = [v_1, v_2, \dots, v_\infty]$ in an ∞ dimensional *inner product vector space*
2. *Inner product* $U \cdot V = \sum_{k=1}^{\infty} u_k v_k$
3. *Norm* $\|U\| = \sqrt{U \cdot V} = \sqrt{\sum v_k^2}$ (the norm is the length of the vector)

- From these definitions we may define the minimum difference between the two vectors as the perpendicular from the end of one to the intersection of the second. As shown in Fig. 3.2, $U \perp V$ may be found by minimizing the length of the vector difference:

$$\begin{aligned} \min_{\alpha} \|V - \alpha U\|^2 &= \|V\|^2 + 2\alpha V \cdot U + \alpha^2 \|U\|^2 > 0 \\ 0 &= \partial_{\alpha} (V - \alpha U) \cdot (V - \alpha U) \\ &= V \cdot U - \alpha^* \|U\|^2 \\ \therefore \alpha^* &= V \cdot U / \|U\|^2. \end{aligned}$$

- The *Schwarz inequality* follows:

$$\begin{aligned} I_{\min} = \|V - \alpha^* U\|^2 &= \|V\|^2 - \frac{|U \cdot V|^2}{\|U\|^2} > 0 \\ 0 &\leq |U \cdot V| \leq \|U\| \|V\| \end{aligned}$$

Thus the direction cosine between the two vectors is

$$\cos(\theta) = \frac{U \cdot V}{\|U\| \|V\|}.$$

- Example:

$$U(\omega) = e^{-\omega_0 t} \quad V(\omega) = e^{\omega t} \quad U \cdot V = \int_{\omega} e^{j\omega t} e^{-j\omega_0 t} \frac{d\omega}{2\pi} = \delta(\omega - \omega_0)$$

Figure 3.1: *Move to text* The Schwartz inequality is related to the shortest distance (length of a line) between the ends of the two vectors. $\|U\| = \sqrt{U \cdot U}$ as the dot product of that vector with itself. This theory is widely used in quantum mechanics (Hilbert inner product spaces).

It is a somewhat arbitrary requirement that $a, b, c \in \mathbb{R}$ for the Pythagorean theorem (Eq. 1.1). This seems natural enough since the sides are lengths. But, what if they are taken from the complex numbers, as for the lossy vector wave equation, or the lengths of vectors in \mathbb{C}^n ? Then the equation

³Get this story straight.

generalizes to

$$\mathbf{c} \cdot \mathbf{c} = \|\mathbf{c}\|^2 = \sum_{k=1}^n |c_k|^2,$$

2028 where $\|\mathbf{c}\|^2 = (\mathbf{c}, \mathbf{c})$ is the inner (dot) product of a vector \mathbf{c} with itself, where $\|\mathbf{c}\| = \sqrt{\|\mathbf{c}\|^2}$ is called
 2029 the *norm* of vector \mathbf{c} , akin to a length, as assumed in Fig. ??.

Figure 3.2: The Schwartz inequality is related to the shortest distance (length of a line) between the ends of the two vectors. $\|U\| = \sqrt{(U \cdot U)}$ as the dot product of that vector with itself.

2030 **Power vs. power series, linear vs. nonlinear**

Another place where equations of second degree appear in physical applications is in energy and power calculations. The electrical power is given by the product of the voltage $v(t)$ and current $i(t)$ (or in mechanics as the force times the velocity). For example if we define $\mathcal{P} = v(t)i(t)$ to be the power \mathcal{P} [Watts], then the *total energy* [Joules] at time t is (Van Valkenburg, 1964a, Chapter 14)

$$\mathcal{E}(t) = \int_0^t v(t)i(t)dt.$$

From this observe that the power is the rate of change of the total energy

$$\mathcal{P}(t) = \frac{d}{dt}\mathcal{E}(t).$$

Ohm's Law and impedance: The ratio of voltage over the current is call the *impedance* which has units of [Ohms]. For example given a resistor of $R = 10$ [ohms],

$$v(t) = R i(t).$$

Namely 1 amp flowing through the resistor would give 10 volts across it. Merging the linear relation due to Ohm's law with the definition of power, shows that the instantaneous power in a resistor is quadratic in voltage and current

$$\mathcal{P} = v(t)^2/R = i(t)^2R.$$

2031 Note that Ohm's law is linear in its relation between voltage and current whereas the power and energy
 2032 are *nonlinear*.

2033 Ohm's Law generalizes in a very important way, allowing the impedance (e.g., resistance) to be
 2034 a linear complex analytic function of complex frequency $s = \sigma + \omega j$ (Kennelly, 1893; Brune, 1931a).
 2035 Impedance is a fundamental concept in many fields of engineering. For example:⁴ Newton's second law
 2036 $F = ma$ obeys Ohm's law, with mechanical impedance $Z(s) = sm$. Hooke's Law $F = kx$ for a spring
 2037 is described by a mechanical impedance $Z(s) = k/s$. In mechanics a "resistor" is called a *dashpot* and
 2038 its impedance is a positive and real constant.⁵

Force is a vector.
voltage are a pote

⁴In acoustics the pressure is a potential, like voltage. The force per unit area is given by $f = -\nabla p$ thus $F = -\int \nabla p dS$. Velocity is analogous to a current. In terms of the velocity potential, the velocity per unit area is $v = -\nabla \phi$.

⁵https://en.wikipedia.org/wiki/Impedance_analogy

2039 **Kirchhoff's Laws KCL, KVL:** The laws of electricity and mechanics may be written down using
 2040 Kirchoff's Laws current and voltage laws, (KCL, KVL), which lead to linear systems of equations in
 2041 the currents and voltages (velocities and forces) of the system under study, with complex coefficients
 2042 having positive real parts.

2043 Points of major confusion are a number of terms that are misused, and overused, in the fields of
 2044 mathematics, physics and engineering. Some of the most obviously abused terms are *linear/nonlinear*,
 2045 *energy, power, power series*. These have multiple meanings, which can, and are, fundamentally in
 2046 conflict.

Transfer functions (Transfer matrix): The only method that seems to work, to sort this out, is to cite the relevant physical application, in specific contexts. The most common touch point is a physical system that has an input $x(t)$ and an output $y(t)$. If the system is linear, then it may be represented by its *impulse response* $h(t)$. In such cases the system equation is

$$y(t) = h(t) \star x(t) \leftrightarrow Y(\omega) = H(s)|_{\sigma=0} X(\omega),$$

2047 namely the convolution of the input with the impulse response gives the output. From Fourier analysis
 2048 this relation may be written in the real frequency domain as a product of the Laplace transform of the
 2049 impulse response, evaluated on the ωj axis and the Fourier transform of the input $X(\omega) \leftrightarrow x(t)$ and
 2050 output $Y(\omega) \leftrightarrow y(t)$.

2051 **Mention ABCD Transfer matrix**

2052 If the system is nonlinear, then the output is not given by a convolution, and the Fourier and
 2053 Laplace transforms have no obvious meaning.

2054 The question that must be addressed is why is the power said to be nonlinear whereas a power series
 2055 of $H(s)$ said to be linear. Both have powers of the underlying variables. This is massively confusing,
 2056 and must be addressed. The question will be further addressed in Section 3.5.1 in terms of the system
 2057 postulates of physical systems.

2058 **Whats going on? The domain variables must be separated from the codomain variables. In our**
 2059 **example, the voltage and current are multiplied together, resulting in a nonlinear output, the power.**
 2060 **If the frequency is squared, this is describing the degree of a polynomial. This is not nonlinear because**
 2061 **it does not impact the signal output, it characterizes the Laplace transform of the system response.**

2062 3.2.2 Lec 13 Root classification of polynomials

2063 **Root classification for polynomials of Degree * = 1-4 (p.102);**

2064 **Quintic (* = 5) cannot be solved: Why?**

2065 **Fundamental Thm of Algebra (d'Alembert, ≈1760)**

2066

2067 **Add intro & merge convolution discussions.**

2068 Convolution

2069 As we discussed in Chapter 1, given the roots, the construction of higher degree polynomials, is greatly
 2070 assisted by the convolution method. This has physical meaning, and gives insight into the problem of
 2071 factoring higher order polynomials. By this method we can obtain explicit relations for the coefficients
 2072 of any polynomial in terms of its roots.

Extending the example of Section 1.3.3, let's find the relations for the cubic. For simplicity, assume that the polynomial has been normalized so that the lead x^3 term has coefficient 1. Then the cubic in terms of its roots $[a, b, c]$ is a convolution of three terms

$$[1, a] \star [1, b] \star [1, c] = [1, a + b, ab] \star [1, c] = [1, a + b + c, ab + c(a + b), abc].$$

Working out the coefficients for a *quartic* gives

$$[1, a+b+c, ab+c(a+b), abc] \star [1, d] = [1, a+b+c+d, d(a+b+c)+c(a+b)+ab, d(ab+ac+bc)+abc, abcd].$$

2073 It is clear what is going on here. The coefficient on x^4 is 1 (by construction). The coefficient for x^3 is
 2074 the sum over the roots. The x^2 term is the sum over all possible products of pairs of roots, The linear
 2075 term x is the sum over all triple products of the four roots, and finally the last term (a constant) is the
 2076 product of the four roots.

2077 In fact this is a well known, a frequently quoted result from the mathematical literature, and trivial
 2078 to show given an understand of convolution. If one wants the coefficients for the quintic, it is not even
 2079 necessary to use convolution, as the pattern (rule) for all the coefficients is now clear.

2080 You can experiment with this numerically using Matlab's convolution routine `conv(a,b)`. Once
 2081 we start studying Laplace and Fourier transforms, convolution becomes critically important because
 2082 multiplying an input signal in the frequency domain by a transfer function, also a function of frequency,
 2083 is the same a convolution of the time domain signal with the inverse Laplace transform of the transfer
 2084 function. So you didn't need to learn how to take a Laplace transform, and then learn convolution.
 2085 We have learned convolution first independent of the Fourier and Laplace transforms.

2086 When the coefficients are real, the roots must appear as conjugate pairs. This is an important
 2087 symmetry.

For the case of the quadratic we have the relations between the coefficients and the roots, found by completing the square. This required isolating x to a single term, and solving for it. We then proceeded to find the coefficients for the cubic and quartic case, after a few lines of calculation. For the quartic

$$\begin{aligned} a_4 &= 1 \\ a_3 &= a + b + c + d \\ a_2 &= d(a + b + c) + c(a + b) + ba \\ a_1 &= d(ab + ac + bd) + abc \\ a_0 &= abcd \end{aligned}$$

2088 These relationships are algebraically nonlinear in the roots. From the work of Galois, for $N \geq 5$, this
 2089 system of equations is impossible to invert. Namely, given a_k , one may not determine the four roots
 2090 $[a, b, c, d]$ analytically. One must use numeric methods.

To gain some insight, let us look at the problem for $N = 2$, which has a closed form solution:

$$\begin{aligned} a_2 &= 1 \\ a_1 &= a + b \\ a_0 &= ab \end{aligned}$$

2091 We must solve for $[a, b]$ given twice the mean, $2(a+b)/2$, and the square of the geometric mean $(\sqrt{ab})^2$.
 2092 Since we already know the answer (i.e, the quadratic formula). The solution was first worked out by the
 2093 Babylonians (2000 BCE) Stillwell (2010, p. 92). It is important to recognize that for physical systems,
 2094 the coefficients a_k are real. This requires that the roots come in conjugate pairs ($b = a^*$), thus $ab = |a|^2$
 2095 and $a + b = 2\Re a$, which makes the problem somewhat more difficult, due to the greater symmetry.

2096 Once you have solved this problem, feel free to attempt the cubic case. Again, the answer is known,
 2097 after thousands of years of searching. The solution to the cubic is given in (Stillwell, 2010, pp. 97-9),
 2098 as discovered by Cardano in 1545. According to Stillwell "The solution of the cubic was the first
 2099 clear advance in mathematics since the time of the Greeks." The ability to solve this problem required
 2100 algebra, and the solutions were complex numbers. The denial of complex numbers was, in my view, the
 2101 main stumbling block in the progress of these solutions. For example, how can two parallel lines have
 2102 a solution? Equally mystifying, how can a circle and a line, that do not intersect, have intersections?
 2103 From the algebra we know that they do. This was a basic problem that needed to be overcome. This

2104 story is still alive,⁶ because the cubic solution is so difficult.⁷ One can only begin to imagine how much
 2105 more difficult the quartic is, solved by Cardano's student Ferrair, and published by Cardano in 1545.
 2106 The impossibility of the quintic was finally resolved in 1826 by Able (Stillwell, 2010, p. 102).

2107 Finally with these challenges behind them, Analytic Geometry, relating of algebra and geometry,
 2108 via coordinate systems, was born.

2109 3.2.3 Lec 14: Analytic Geometry

2110 Lec 14: Early Analytic Geom (Merging Euclid and Descartes): Composition of degrees n, m gives
 2111 degree $m \cdot n$

2112 Composition and Intersection (Gaussian elimination)

2113 The first "algebra" (al-jabr) is credited to al-Khwarizmi (830 CE). Its invention advanced the theory
 2114 of polynomial equations in one variable, Taylor series, and composition versus intersections of curves.
 2115 The solution of the quadratic equation had been worked out thousands of year earlier, but with algebra
 2116 a general solution could be defined. The Chinese had found the way to solve several equations in
 2117 several unknowns, for example, finding the values of the intersection of two circles. With the invention
 2118 of algebra by al-Khwarizmi, a powerful tool became available to solve the difficult problems.

2119 **Composition, Elimination and Intersection** In algebra there are two contrasting operations on
 2120 functions: *composition* and *Elimination*, (aka *intersection*).

2121 **Composition:** Composition is the merging of functions, by feeding one into the other. If the two
 2122 functions are f, g then their composition is indicated by $f \circ g$, meaning the function $y = f(x)$ is
 2123 substituted into the function $z = g(y)$, giving $z = g(f(x))$.

2124 Composition is not limited to linear equations, even though that is where it is most frequently
 2125 applied. To compose two functions, one must substitute one equation into the other. That requires
 2126 solving for that substitution variable, which is not always possible in the case of nonlinear equations.
 2127 However many tricks are available that may work around this restrictions. For example if one equation
 2128 is in x^2 and the other in x^3 or \sqrt{x} , it may be possible to multiply the first by x or square the second.
 2129 The point is that one of the variables must be isolated so that when it is substituted into the other
 2130 equations, the variable is removed from the mix.

Examples: Let $y = f(x) =: x^2 - 2$ and $z = g(y) =: y + 1$. Then

$$g \circ f = g(f(x)) = (x^2 - 2) + 1 = x^2 - 1. \quad (3.5)$$

In general composition does not commute (i.e., $f \circ g \neq g \circ f$), as is easily demonstrated. Swapping the order of composition for our example gives

$$f \circ g = f(g(y)) = z^2 - 2 = (y + 1)^2 - 2 = y^2 + 2y - 1. \quad (3.6)$$

2131 **Intersection:** Complimentary to composition is *intersection* (i.e., decomposition) (Stillwell, 2010,
 2132 pp. 119,149). For example, the intersection of two lines is defined as the point where they meet. This
 2133 is not to be confused with finding roots. A polynomial of degree N has N roots, but the points where
 2134 two polynomials intersect has nothing to do with the roots of the polynomials. The intersection is a
 2135 function (equation) of lower degree, implemented with Gaussian elimination.

⁶M. Kac, *How I became a mathematician.* *American Scientist* (72), 498–499.

⁷<https://www.google.com/search?client=ubuntu&channel=fs&q=Kac+%22how+I+became+a%22+1984+pdf&ie=utf-8&oe=utf-8>

Intersection of two lines Unless they are parallel, two lines meet at a point. In terms of linear algebra this may be written as 2 linear equations (left) along with the intersection point $[x_1, x_2]^T$, given by the inverse of the 2x2 set of equations (right).⁸

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \qquad \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad (3.7)$$

where $\Delta = ab - cd$ is called the *determinant*. By substituting the right expression into the left, and taking the inverse we obtain the intersection point. If $\Delta = 0$ there can be no solution, in which case the two lines are parallel (they meet at infinity.)

Algebra will give the solution when geometry cannot. When the two curves fail to intersect on the real plane, the solution still exists, but is complex valued. In such cases, geometry, which only considers the real solutions, fails. For example, when the coefficients $[a, b, c, d]$ are complex, the solution exists, but the determinant can be complex. Thus algebra is much more general than geometric. Geometry fails when the solution has a complex intersection.

3.3 Week 6

3.3.1 Lec 15 Gaussian Elimination (Intersection)

Example problems using Gaussian Elimination: Gaussian Elimination is valid for nonlinear systems of equations. Till now we have emphasized the reduction of linear systems of equations.

Problem 1: Two lines *in a plane* either intersect or are parallel, in which case they are said to meet at ∞ . Does this make sense? The two equations that describe this may be written in matrix form as $Ax = b$, which written out as

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix} \quad (3.8)$$

The intersection point x_0, y_0 is given by the solution two these two equations

$$\begin{bmatrix} x_1 \\ x_1 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix} \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}, \quad (3.9)$$

⁸It is very important to note when writing the equations in matrix format, the unknowns are x_1, x_2 whereas in the original equations they were y, x . The starting equations are $ay_1 + bx_1 = c$ and $cy_1 + dx_2 = d$ but in matrix format the names are changed. The first equation is $ax_1 + bx_2 = y_1$ and $cx_1 + dx_2 = y_2$. The first time you meet this scrambling of terminology it can be very confusing. In matrix equations the coordinates of the graph are (x_1, x_2) rather than the usual x, y .

2157 where $\Delta = a_{11}a_{22} - a_{12}a_{21}$ is the determinant of matrix A (Matlab's `det(A)` function).

It is useful to give an interpretation of these two equations. Each row of the 2x2 matrix defines a line in the (x, y) plane. The top row is

$$a_{11}x + a_{12}y = b_1.$$

Normally we would write this equation as $y(x) = \alpha x + \beta$, where α is the slope and β is the *intercept* (i.e., $y(0) = \beta$). In terms of the elements of matrix A , the slope of the first equation is $\alpha = -a_{11}/a_{12}$ while the slope of the second is $\alpha = -a_{21}/a_{22}$. The two slopes are equal (the lines are parallel) when $-a_{11}/a_{12} = -a_{21}/a_{22}$, or written out

$$\Delta = a_{11}a_{22} - a_{12}a_{21} = 0.$$

2158 Thus when the determinate is zero, the two lines are parallel and there is no solution to the equations.

This 2x2 matrix equation is equivalent to a 2^d degree polynomial. If we seek an eigenvector solution $[e_1, e_2]^T$ such that

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \end{bmatrix} = \lambda \begin{bmatrix} e_1 \\ e_2 \end{bmatrix} \quad (3.10)$$

the 2x2 equation becomes singular, and λ is one of the roots of the polynomial. One may proceed by merging the two terms to give

$$\begin{bmatrix} a_{11} - \lambda & a_{12} \\ a_{21} & a_{22} - \lambda \end{bmatrix} \begin{bmatrix} e_1 \\ e_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \quad (3.11)$$

Clearly this new matrix has no solution, since if it did, $[e_1, e_2]^T$ would be zero, which is nonsense. If it has no solution, then the determinant of the matrix must be zero. Forming this determinate gives

$$(a_{11} - \lambda)(a_{22} - \lambda) - a_{12}a_{21} = 0$$

thus we obtain the following quadratic equation for the roots λ_{\pm} (eigenvalues)

$$\lambda_{\pm}^2 - (a_{11} + a_{22})\lambda_{\pm} + \Delta = 0.$$

2159 When $\Delta = 0$, one eigenvalue is zero while the other is $a_{11} + a_{22}$, which is known as the *trace* of the
2160 matrix.

2161 **In summary:** Given a “linear” equation for the point of intersection of two lines, we see that there
2162 must be two points of intersection, as there are always two roots of the quadratic *characteristic poly-*
2163 *nomial*. However the two lines only intersect at one point. Whats going on? What is the meaning of
2164 this second root?

Needs work. 2164
2165 Some simple examples will help. The eigenvalues depend on the relative slopes of the lines, which
2166 in general can become complex. The intercepts are dependent on \mathbf{b} . Thus when the RHS is zero, the
2167 eigenvalues are irrelevant. This covers the very simple examples. When one eigenvalue is real and the
2168 other is imaginary, more interesting things are happening since the slope of one line is real and the
2169 slope of the other is pure imaginary. The lines can intersect in the real plane, and again in the complex
2170 plane.

Lets try an example of two lines, slopes of 1 and 2: $y_1 = x + a$ and $y_2 = 2x + b$. In matrix form Let

$$\begin{bmatrix} 1 & -1 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} y \\ x \end{bmatrix} = \begin{bmatrix} a \\ b \end{bmatrix} \quad (3.12)$$

The determinate is $\Delta = -1$, thus the solution is

$$\begin{bmatrix} y_0 \\ x_0 \end{bmatrix} = -1 \begin{bmatrix} -2 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} 2 & -1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} 2a - b \\ a - b \end{bmatrix}. \quad (3.13)$$

2171 Thus the two real lines having slopes of 1 and 2 having intercepts of a and b , meet $(x_0, y_0) = (2a-b, a-b)$.
 2172 We may verify by substituting $x = a - b$ into the starting equations $y_1 = (a - b) + a = 2a - b$ and
 2173 $y_2 = 2(a - b) + b = 2a - b$, which each $2a - b$.

While there is a unique solution, there are two eigenvalues, given by the roots of

$$(1 - \lambda_{\pm})(-2 - \lambda_{\pm}) + 1 = 0.$$

If we transfer the sign from one monomial to the other

$$(-1 + \lambda_{\pm})(2 + \lambda_{\pm}) + 1 = 0$$

and reorder for simplicity

$$(\lambda_{\pm} - 1)(\lambda_{\pm} + 2) + 1 = 0$$

we obtain the quadratic for the roots

$$\lambda_{\pm}^2 + \lambda_{\pm} - 1 = 0.$$

Completing the square gives

$$(\lambda_{\pm} + 1/2)^2 = 3/4.$$

or

$$\lambda_{\pm} = -1/2 \pm \sqrt{3}/2.$$

2174 The question is, what is the relationship between the eigenvalues and the final solution, if any? Maybe
 2175 none. The solution (x_0, y_0) is reasonable, and its not clear that the eigenvalues play any useful role
 2176 here, other than to predict there is a second solution. I'm confused.

Two lines in 3-space: In three dimensions

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix} \quad (3.14)$$

2177 Each row of the matrix describes a plane, which is said to be linear in the unknowns (x, y, z) . Thus the
 2178 system of linear equations represents three planes, which must intersect at one point. If two planes are
 2179 parallel, there is no real solution. In this case the intersection by the third plane generates two parallel
 2180 lines.

2181 As in the 2x2 case, one may convert this linear equation into a cubic polynomial by setting the
 2182 determinant of the matrix, with $-\lambda$ subtracted from the diagonal, equal to zero. That is, $\det(A - \lambda I) =$
 2183 0 . Here I is the matrix with 1 on the diagonal and zero off the diagonal.

Simple example: As a simple example, let the first plane be $z = 0$ (independent of x, y), the second
 parallel plane be $z = 1$ (independent of (x, y)) and the third plane be $x = 0$ (independent of y, z). This
 results in the system of equations

$$\begin{bmatrix} 0 & 0 & a_{13} \\ 0 & 0 & a_{23} \\ a_{31} & 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} \quad (3.15)$$

2184 Writing out the three equations we find $a_{13}z = 0$, $a_{23}z = 1$, and $a_{31}x = 0$. Note that $\det(A) = 0$ (we
 2185 need to learn how to compute the 3x3 determinant). This means the three planes never intersect at
 2186 one point. Use Matlab to find the eigenvalues.

2187 3.3.2 Lec 16 Matrix composition: Bilinear and ABCD transformations

2188 The Transmission matrix

A transmission matrix is a 2x2 matrix that characterizes a 2-port circuit, one having an input and output voltage and current, as shown in Fig. 1.11. The input is the voltage and current V_1, I_1 and the output is the voltage and current $V_2, -I_2$, with the current always defined to flow into the port. For any such a linear network, the input-output relations may be written in a totally general way as

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} A(s) & B(s) \\ C(s) & D(s) \end{bmatrix} \begin{bmatrix} V_2 \\ -I_2 \end{bmatrix}.$$

2189 In Section 1.3.6 we showed that a cascade of such matrices is composition. We shall show below that
2190 the justification of this relationship is based on the composition of bilinear transformations.

Expanding Eq. 1.27 into its individual equations demonstrates the linear form of the relations

$$V_1 = A(s)V_2 - B(s)I_2 \qquad I_1 = C(s)V_2 - D(s)I_2,$$

2191 quantifying the relationship between the input voltage and current to its output voltage and current.

2192 Define $H(s) = V_2/V_1$ as the *transfer function*, as the ratio of the output voltage V_2 over the input
2193 voltage V_1 , under the constraint that the output current $I_2 = 0$. From this definition $H(s) = 1/A(s)$.

In a similar fashion we may define the meaning of all four functions as

$$A(s) \equiv \left. \frac{V_1}{V_2} \right|_{I_2=0} \qquad B(s) \equiv \left. -\frac{V_1}{I_2} \right|_{V_2=0} \qquad (3.16)$$

$$C(s) \equiv \left. \frac{I_1}{V_2} \right|_{I_2=0} \qquad D(s) \equiv \left. -\frac{I_1}{I_2} \right|_{V_2=0} \qquad (3.17)$$

2194 From Eq. 1.27 one may compute any desired quantity, specifically those quantities defined in
2195 Eq. 3.17, the open circuit voltage transfer function ($1/A(s)$), the short-circuit transfer current ($1/D(s)$)
2196 and the two transfer impedances $B(s)$ and $1/C(s)$.

2197 In the engineering fields this matrix composition is called the *Transmission matrix*, also known as
2198 the ABCD method. It is a powerful method that is easy to learn and use, that gives important insights
2199 into transmission lines, and thus even the 1 dimensional wave equation.

2200 Derivation of ABCD matrix for example of Fig. 1.11.

2201 The derivation is straight forward by the application of Ohm's Law, as shown in Section 1.3.6.

The convenience of the ABCD matrix method is that the output of one is identically the input of the next. Cascading (composing) the results for the series inductor with the shunt compliance leads to the 2x2 matrix form that precisely corresponds to the transmission line CFA shown in Fig. 2.2,

$$\begin{bmatrix} V_n(s) \\ I_n(s) \end{bmatrix} = \begin{bmatrix} 1 & sL_n \\ 1 & 0 \end{bmatrix} \begin{bmatrix} V_{n+1}(s) \\ -I_{n+1}(s) \end{bmatrix}. \qquad (3.18)$$

This matrix relation characterizes the series mass term sL_n . A second equation maybe be used for the shunt capacitance term $sY_n(s)$

$$\begin{bmatrix} V_n(s) \\ I_n(s) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ sC_n & 0 \end{bmatrix} \begin{bmatrix} V_{n+1}(s) \\ -I_{n+1}(s) \end{bmatrix}. \qquad (3.19)$$

2202 The positive constants $L_n, C_n \in \mathbb{R}$ represent the series mass (inductance) and the shunt compliance
2203 (capacitance) of the mechanical (electrical) network. The integer n indexes the series and shunt sections,
2204 that are composed one following the next.

2205 **Matrix composition and the bilinear transform:** Now that we have defined the composition of
 2206 two functions, we will use it to define the *Möbius* or *bilinear* transformation. Once you understand how
 2207 this works, hopefully you will understand why it is the unifying element in many important engineering
 2208 problems.

The bilinear transformation is given by

$$w = \frac{a + bz}{c + dz}$$

This takes one complex number $z = x + iy$ and transforms it into another complex number $w = u + iv$. This transformation is *bilinear* in the sense that its linear in both the input and output side of the equation. This may be seen when written as

$$(c + dz)w = a + bz,$$

since this relation is linear in the coefficients $[a, b, c, d]$. An important example is the transformation between impedance $Z(s)$ and reflectance $\Gamma(s)$,

$$\Gamma(s) = \frac{Z(s) - r_0}{Z(s) + r_0},$$

2209 which is widely used in transmission line problems. In this example $w = \Gamma, z = Z(s), a = -r_0, b =$
 2210 $1, c = r_0, d = 1$.

If we define a second bilinear transformation (this could be the transformation from reflectance back to impedance)

$$r = \frac{\alpha + \beta w}{\gamma + \delta w},$$

and then compose the two **something astray wrt arguments**

$$w \circ r = \frac{a + b r}{c + d r} = \frac{a(\gamma + \delta w) + b(\alpha + \beta w)}{c(\gamma + \delta w) + d(\alpha + \beta w)} = \frac{a\gamma + b\alpha + (a\delta + b\beta)w}{c\gamma + d\alpha + (c\delta + d\beta)w},$$

something surprising happens. The composition $w \circ r$ may be written in matrix form, as the product of two matrices that represents each bilinear transform. This may be seen as true by inspecting the coefficients of the composition $w \circ r$ (shown above) and the product of the two matrices

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} = \begin{bmatrix} (a\gamma + b\alpha) & (a\delta + b\beta) \\ (c\gamma + d\alpha) & (c\delta + d\beta) \end{bmatrix}.$$

2211 The the power of this composition property of the bilinear transform may be put to work solving
 2212 important engineering problems, using *transmission matrices*.

2225 3.4 Week 7

2226 3.4.1 Lec 18 Complex analytic mappings (colorized plots)

2227 Colorized plots (Matlab *zviz.m*)

2228
2229 When one uses complex analytic functions it is helpful to understand their properties in the complex
2230 plane. In this sections we explore several well-known functions using colorized plots.

Figure 3.4: On the left is the function $w(s) = s^2$ and on the right is $s = \sqrt{w}$.

2231 In the first example (Fig. 3.4) we look at $w(s) = s^2$ and its inverse $s(w) = \sqrt{w}$. On the left we see
 2232 that the red region, corresponding to 0° [degrees] appears at both 0 and 180 in the w plane. This is
 2233 because in polar coordinates $s^2 = |s|^2 e^{2\theta j}$ where θ is the angle of $s = |s|e^{2\theta j}$. Note also that the black
 2234 spot is dilated due to the squaring of the radius (expanding it). On the right the $\sqrt{w} = \sqrt{|w|}e^{\phi/2}$.
 2235 Because the angle of w is divided by two, it takes twice as much phase (in w) to cover the same angle.
 2236 Thus the red region (0°) is expanded. We barely see the violet 90° and yellow -90° angles. There
 2237 is a *branch cut* running from $w = 0$ to $w = \infty$. As the branch cut is crossed, the function switches
 2238 *Riemann sheets*, going from the top sheet (shown here) to the bottom sheet (not shown). Figure 3.3 in
 2239 Section 3.3.3 depicts what is going on with these two sheets, and show the branch cut from the origin
 2240 (point O) to ∞ . In this depiction the first sheet ($+\sqrt{z}$) is on the bottom, while the second sheet (\sqrt{z})
 2241 is on top. For every value of z there are two possible outcomes, $\pm\sqrt{z}$, represented by the two sheets.

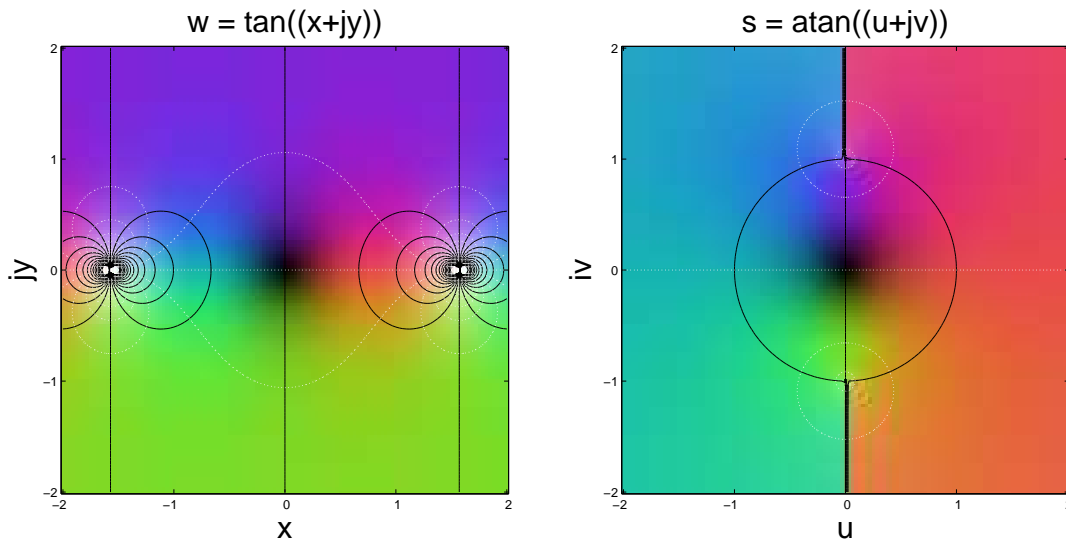

Figure 3.5: On the left is the function $w(s) = \tan(z)$ and on the right is its inverse $w(s) = \tan^{-1}(\pi s)$.

2242 In the second example (Fig. 3.5) we show $w = \tan(z)$ and its inverse $z = \tan^{-1}(w)$. The tangent
 2243 function has zeros where $\sin(z)$ has zeros (e.g., at $z = 0$) and poles where $\cos(z)$ is zero (e.g., at $\pm\pi/2$).
 2244 The inverse function $s = \text{atan}(w)$ has a zero at $w = 0$ and branch cuts eliminating from $z = \pm\pi$.

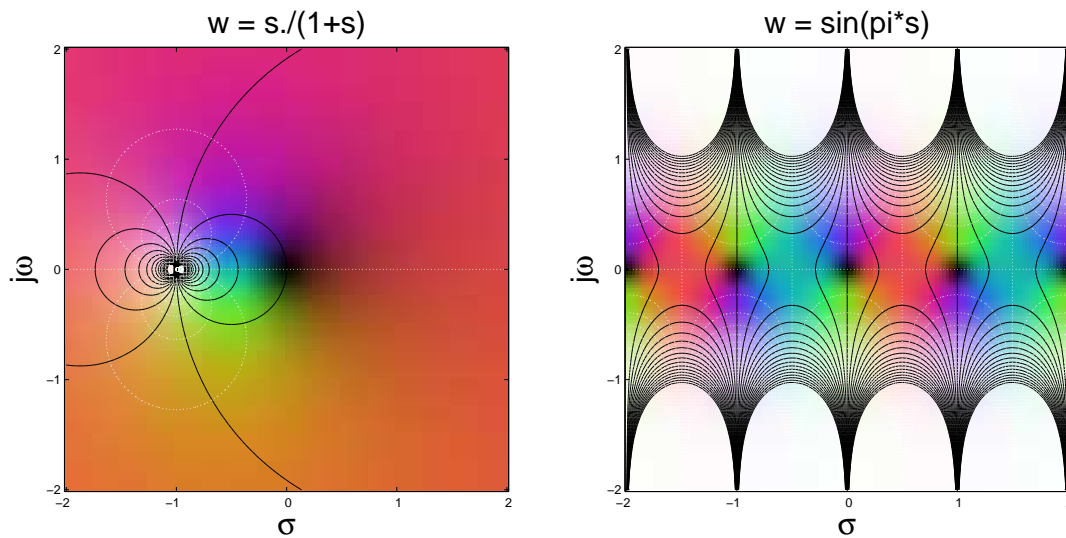

Figure 3.6: On the left is the function $w(s) = s/(1 + s)$, having a zero at $s = 0$ and a pole at $s = -1$. On the right is $w(s) = \sin(\pi s)$. See the discussion in the text for an interpretation of these complex maps.

Two more examples are given in Fig. 3.6 to interpret the two complex mappings $w = s/(1 + s)$ (left) and $w = \sin(\pi s)$ (right). On the left is $s/(1 + s)$ which is a zero at $s = 0$, resulting in a dark spot, and a pole at $s = -1$ resulting in a white spot. Note how the white and black contour lines are always perpendicular where they cross, just as in the calibration plots for the x and y axes, shown in Fig. 1.13 in Section 1.3.8 (p. 56).

The right-hand plot of $w(s) = \sin(\pi s)$ is equally interesting. Along the σ axis (real part of s) the function is the periodic $\sin(\sigma)$ function. The dark spots are at $\sigma = k\pi$, with $k \in \mathbb{Z}$. This is the normal $\sin(\pi\sigma)$ function with zeros at $0, \pm\pi, 2 \pm \pi, \dots$. When we stray off the $\omega_j = 0$ axis, the function either goes to zero (black) or ∞ (white). This behavior carries the same 2π periodicity as it has along the $\omega = 0$ line. These figure are worthy of careful study to develop an intuition for complex functions of complex variables. In Section 1.3.8 we shall explore more complex mappings, and in greater detail.

It becomes most interesting to study polynomials of degree 5 and 4, with one zero removed, to demonstrate the Fundamental Theorem of Algebra. Recall that degree 5 is not analytically tractable, and must be investigated numerically.

Discuss the branch cut.

3.5 Week 8

3.5.1 Lec 21 The 9 postulates of System of algebraic Networks

Taxonomy requires a proper statement of the laws of physics, which includes at least the nine basic network postulates described in Section 1.3.11. To describe each of the network postulates one must start from the Transmission matrix representation discussed in Section 3.3.2.

The 2-port *transmission matrix* for an acoustic transducer (loudspeaker) shown in Fig. 3.7 is defined as

$$\begin{bmatrix} \Phi_i \\ I_i \end{bmatrix} = \begin{bmatrix} A(s) & B(s) \\ C(s) & D(s) \end{bmatrix} \begin{bmatrix} F_l \\ -U_l \end{bmatrix} = \frac{1}{T} \begin{bmatrix} z_m(s) & z_e(s)z_m(s) + T^2 \\ 1 & z_e(s) \end{bmatrix} \begin{bmatrix} F_l \\ -U_l \end{bmatrix}. \quad (3.20)$$

The input is electrical (voltage and current) $[\Phi_i, I_i]$ and the output (load) are the mechanical (force and velocity) $[F_l, U_l]$. The first matrix is the general case, expressed in terms of four unspecified functions $A(s), B(s), C(s), D(s)$, while the second matrix is for the specific example of Fig. 3.7. The four entries

Figure 3.7: A schematic representation of a 2-port ABCD electro-mechanic system using Hunt parameters $Z_e(s)$, $z_m(s)$, and $T(s)$: electrical impedance, mechanical impedances, and transduction coefficient (Hunt, 1952; Kim and Allen, 2013). Also $V(f)$, $I(f)$, $F(f)$, and $U(f)$ are the frequency domain voltage, current, force, and velocity respectively. Notice how the matrix method ‘factors’ the 2-port model into three 2×2 matrices. This allows one to separate the physical modeling from the algebra. It is a standard impedance convention that the flows $I(f)$, $U(f)$ are always defined into the port. Thus it is necessary to apply a negative sign on the velocity $-U(f)$ so that it has an outward flow, to feed the next cell with an inward flow. **Replace Φ with V .**

2279 are the electrical driving point impedance $Z_e(s)$, the mechanical impedance $z_m(s)$ and the transduction
 2280 $T = B_0 l$ where B_0 is the magnetic flux strength and l is the length of the wire crossing the flux. Since
 2281 the transmission matrix is anti-reciprocal, its determinate $\Delta_T = -1$, as is easily verified.

2282 Other common transduction examples of cross-modality transduction include current–thermal (ther-
 2283 moelectric effect) and force–voltage (piezoelectric effect). These systems are all reciprocal, thus the
 2284 transduction has the same sign.

2285 **Impedance matrix**

These nine postulates describe the properties of a system having an input and an output. For the case of an electromagnetic transducer (Loudspeaker) the system is described by the 2-port, as show in Fig. 3.7. P6 is inherently a 2-port network property, while P1-P5 also apply to 1-ports networks (e.g., a driving point impedance is a 1-port). For example the electrical input impedance of a loudspeaker is $Z_e(s)$, defined by

$$Z_e(s) = \left. \frac{V(\omega)}{I(\omega)} \right|_{U=0}.$$

2286 Note that this *driving-point impedance* must be causal, thus it has a Laplace transform and therefore is
 2287 a function of the complex frequency $s = \sigma + j\omega$, whereas the Fourier transforms of the voltage $V(\omega)$ and
 2288 current $I(\omega)$ are functions of the real radian frequency ω , since the time-domain voltage $v(t) \leftrightarrow V(\omega)$
 2289 and the current $i(t) \leftrightarrow I(\omega)$ are signals that may start and stop at any time (they are not typically
 2290 causal).

The corresponding 2-port *impedance matrix* for Fig. 3.7 is

$$\begin{bmatrix} \Phi_i \\ F_l \end{bmatrix} = \begin{bmatrix} z_{11}(s) & z_{12}(s) \\ z_{21}(s) & z_{22}(s) \end{bmatrix} \begin{bmatrix} I_i \\ U_l \end{bmatrix} = \begin{bmatrix} Z_e(s) & -T(s) \\ T(s) & z_m(s) \end{bmatrix} \begin{bmatrix} I_i \\ U_l \end{bmatrix}. \quad (3.21)$$

2291 The impedance matrix is an alternative description of the system but with generalized forces $[\Phi_i, F_l]$
 2292 on the left and generalized flows $[I_i, U_l]$ on the right. A rearrangement of the equations allows one
 2293 to go from one set of parameters to the other (Van Valkenburg, 1964b). Since the electromagnetic
 2294 transducer is anti-reciprocal, $z_{12} = -z_{21} = T = B_0 l$. Such a description allows one to define *Thèvenin*
 2295 *parameters*, a very useful concept used widely in circuit analysis and other network models from other
 2296 modalities.

2297 **Additional or modified postulates**

2298 The postulates must go beyond postulates P1-P6 defined by Carlin and Giordano (Section 1.3.11,
 2299 p. 61), when there are interaction of waves and a structured medium, along with other properties not
 2300 covered by classic network theory. Assuming QS, the wavelength must be large relative to the medium’s
 2301 lattice constants. Thus the QS property must be extended to three dimensions, and possibly to the
 2302 cases of an-isotropic and random media.

2303 **Causality: P1** As stated above, due to causality the negative properties (e.g., negative refractive
 2304 index) must be limited in bandwidth, as a result of the Cauchy-Riemann conditions. However even
 2305 causality needs to be extended to include the delay, as quantified by the d'Alembert solution to the
 2306 wave equation, which means that the delay is proportional to the distance. Thus we generalize P1
 2307 to include the space dependent delay. When we wish to discuss this property we denote it *Einstein*
 2308 *causality*, which says that the delay must be proportional to the distance x , with impulse response
 2309 $\delta(t - x/c)$.

2310 **Linearity: P2** The wave properties of may be non-linear (P2). This is not restrictive as most
 2311 physical systems are naturally nonlinear. For example, a capacitor is inherently nonlinear: as the
 2312 charge builds up on the plates of the capacitor, a stress is applied to the intermediate dielectric due to
 2313 the electrostatic force $F = qE$. In a similar manner, an inductor is nonlinear. Two wires carrying a
 2314 current are attracted or repelled, due to the force created by the flux. The net force is the product of
 2315 the two fluxes due to each current.

2316 In summary, most physical systems are naturally nonlinear, it's simply a matter of degree. An
 2317 important counter example is a amplifier with negative feedback, with very large open-loop gain.
 2318 There are, therefore, many types of non-linear, instantaneous and those with memory (e.g., hysteresis).
 2319 Given the nature of P1, even an instantaneous non-linearity may be ruled out. The linear model is so
 2320 critical for our analysis, providing fundamental understanding that we frequently take this postulate
 2321 for granted.

2322 **Real time response: P3** The impulse response of every physical system is real, vs. complex. This
 2323 requires that the Laplace Transform have conjugate-symmetric symmetry $H(s) = H^*(s^*)$, where the $*$
 2324 indicates conjugation (e.g., $R(\sigma, \omega) + X(\sigma, \omega) = R(\sigma, \omega) - X(\sigma, -\omega)$).

2325 **Passive/Active: P4** We greatly extend P4 by building in the physics behind conservation of energy:
 2326 Otto Brune's *positive Real* (PR aka physically realizable) condition. Following up on the earlier work
 2327 of his primary PhD thesis advisor Wilhelm Cauer (1900-1945), and working with Norbert Weiner and
 2328 Vannevar Bush at MIT, Otto Brune mathematically characterized the properties of every PR 1-port
 2329 driving point impedance.

When the input resistance of the impedance is real, the system is said to be *passive*, which means the system obeys conservation of energy. The real part of $Z(s)$ is positive if and only if the corresponding reflectance is less than 1 in magnitude. The definition of the reflectance of $Z(s)$ is defined as a bilinear transformation of the *impedance*, normalized by its *surge resistance* r_0 (Campbell, 1903)

$$\Gamma(s) = \frac{Z(s) - r_0}{Z(s) + r_0}.$$

The surge resistance is defined in terms of the inverse Laplace transform of $Z(s) \leftrightarrow z(t)$, which must have the form

$$z(t) = r_0\delta(t) + \zeta(t),$$

2330 where $\zeta(t) = 0$ for $t < 0$. It naturally follows that $\gamma(t) \leftrightarrow \Gamma(s)$ is zero for negative and zero time,
 2331 namely $\gamma(0) = 0, t \leq 0$. at

Given any linear PR impedance $Z(s) = R(\sigma, \omega) + jX(\sigma, \omega)$, having real part $R(\sigma, \omega)$ and imaginary part $X(\sigma, \omega)$, the impedance is defined as being PR (Brune, 1931b) if and only if

$$R(\sigma \geq 0, \omega) \geq 0. \quad (3.22)$$

2332 That is, the real part of any PR impedance is non-negative everywhere in the right half s plane ($\sigma \geq 0$).
 2333 This is a very strong condition on the complex analytic function $Z(s)$ of a complex variable s . This
 2334 condition is equivalent to any of the following statements: 1) There are no poles or zeros in the right
 2335 half plane ($Z(s)$ may have poles and zeros on the $\sigma = 0$ axis). 2) If $Z(s)$ is PR then its reciprocal

2336 $Y(s) = 1/Z(s)$ is PR (the poles and zeros swap). 3) If the impedance may be written as the ratio
 2337 of two polynomials (a limited case, related to the quasistatics approximation, P9) having degrees N
 2338 and L , then $|N - L| \leq 1$. 4) The angle of the impedance $\theta \equiv \angle Z$ lies between $[-\pi \leq \theta \leq \pi]$. 5)
 2339 The impedance *and its reciprocal* are *complex analytic* in the right half plane, thus they each obey the
 2340 Cauchy Riemann conditions there.

The PR (positive real or Physically realizable) condition assures that every impedance is *positive-definite* (PD), thus guaranteeing conservation of energy is obeyed (Schwinger and Saxon, 1968, p.17). This means that the total energy absorbed by any PR impedance must remain positive for all time, namely

$$\mathcal{E}(t) = \int_{-\infty}^t v(t)i(t) dt = \int_{-\infty}^t i(t) \star z(t) i(t) dt > 0,$$

2341 where $i(t)$ is *any* current, $v(t) = z(t) \star i(t)$ is the corresponding voltage and $z(t)$ is the real causal
 2342 impulse response of the impedance, e.g., $z(t) \leftrightarrow Z(s)$ are a Laplace Transform pair. In summary, if
 2343 $Z(s)$ is PR, $\mathcal{E}(t)$ is PD.

As discussed in detail by Van Valkenburg, any rational PR impedance can be represented as a *rational polynomial fraction expansion* (residue expansion), which can be expanded into first-order poles as

$$Z(s) = K \frac{\prod_{i=1}^L (s - n_i)}{\prod_{k=1}^N (s - d_k)} = \sum_n \frac{\rho_n}{s - s_n} e^{j(\theta_n - \theta_d)}, \quad (3.23)$$

2344 where ρ_n is a complex scale factor (residue). Every pole in a PR function has only simple poles *and*
 2345 zeros, requiring that $|L - N| \leq 1$ (Van Valkenburg, 1964b).

2346 Whereas the PD property clearly follows P3 (conservation of energy), the physics is not so clear.
 2347 Specifically what is the physical meaning of the specific constraints on $Z(s)$? In many ways, the
 2348 impedance concept is highly artificial, as expressed by P1-P7.

2349 When the impedance is not rational, special care must be taken. An example of this is the semi-
 2350 inductor $M\sqrt{s}$ and semi-capacitor K/\sqrt{s} due, for example, to the *skin effect* in EM theory and viscous
 2351 and thermal losses in acoustics, both of which are frequency dependent boundary-layer diffusion losses.
 2352 They remain positive-real but have a branch cut, thus are double valued in frequency.

2353 By building in the physics behind conservation of energy: Otto Brune's *positive-real* (PR) condition.
 2354 Following up on the earlier work of his primary PhD thesis advisor Wilhelm Cauer (1900-1945), and
 2355 working with Norbert Wiener and Vannevar Bush at MIT, Otto Brune mathematically characterized
 2356 the properties of every PR 1-port driving point impedance (Brune, 1931b).

Given any linear PR impedance $Z(s) = R(\sigma, \omega) + jX(\sigma, \omega)$, having real part (resistance) $R(\sigma, \omega)$ and imaginary part (reactance) $X(\sigma, \omega)$, the impedance is defined as being PR (Brune, 1931a) if and only if

$$R(\sigma \geq 0, \omega) \geq 0. \quad (3.24)$$

2357 That is, the real part of any PR impedance is non-negative everywhere in the right half s plane ($\sigma \geq 0$).
 2358 This is a very strong condition on the complex analytic function $Z(s)$ of a complex variable s . This
 2359 condition is equivalent to any of the following statements: 1) There are no poles or zeros in the right
 2360 half plane ($Z(s)$ may have poles and zeros on the $\sigma = 0$ axis). 2) If $Z(s)$ is PR then its reciprocal
 2361 $Y(s) = 1/Z(s)$ is PR (the poles and zeros swap). 3) If the impedance may be written as the ratio of two
 2362 polynomials (a limited case) having degrees N and L , then $|N - L| \leq 1$. 4) The angle of the impedance
 2363 $\theta \equiv \angle Z$ lies between $[-\pi \leq \theta \leq \pi]$. 5) The impedance *and its reciprocal* are *complex analytic* in the
 2364 right half plane, thus they each obey the Cauchy Riemann conditions.

The PR (positive real or Physically realizable) condition assures that every impedance is *positive-definite* (PD), thus guaranteeing conservation of energy is obeyed (Schwinger and Saxon, 1968, p.17). This means that the total energy absorbed by any PR impedance must remain positive for all time, namely

$$\mathcal{E}(t) = \int_{-\infty}^t v(t)i(t) dt = \int_{-\infty}^t i(t) \star z(t) i(t) dt > 0,$$

2365 where $i(t)$ is *any* current, $v(t) = z(t) \star i(t)$ is the corresponding voltage and $z(t)$ is the real causal
 2366 impulse response of the impedance, e.g., $z(t) \leftrightarrow Z(s)$ are a Laplace Transform pair. In summary, if
 2367 $Z(s)$ is PR, $\mathcal{E}(t)$ is PD.

As discussed in detail by Van Valkenburg, any rational PR impedance can be represented as a *rational polynomial fraction expansion* (residue expansion), which can be expanded into first-order poles as

$$Z(s) = K \frac{\prod_{i=1}^L (s - n_i)}{\prod_{k=1}^N (s - d_k)} = \sum_n \frac{\rho_n}{s - s_n} e^{j(\theta_n - \theta_d)}, \quad (3.25)$$

2368 where ρ_n is a complex scale factor (residue). Every pole in a PR function has only simple poles *and*
 2369 zeros, requiring that $|L - N| \leq 1$ (Van Valkenburg, 1964a).

2370 Whereas the PD property clearly follows P3 (conservation of energy), the physics is not so clear.
 2371 Specifically what is the physical meaning of the specific constraints on $Z(s)$? In many ways, the
 2372 impedance concept is highly artificial, as expressed by P1-P7.

2373 When the impedance is not rational, special care must be taken. An example of this is the semi-
 2374 inductor $M\sqrt{s}$ and semi-capacitor K/\sqrt{s} due, for example, to the *skin effect* in EM theory and viscous
 2375 and thermal losses in acoustics, both of which are frequency dependent boundary-layer diffusion losses.
 2376 They remain positive-real but have a branch cut, thus are double valued in frequency.

2377 **Time invariant: P5** The meaning of *time-invariant* requires that the impulse response of a system
 2378 does not change over time. This requires that the system coefficients of the differential equation
 2379 describing the system are constant (independent of time).

Rayleigh Reciprocity: P6 Reciprocity is defined in terms of the unloaded output voltage that results from an input current. Specifically

$$\begin{bmatrix} z_{11}(s) & z_{12}(s) \\ z_{21}(s) & z_{22}(s) \end{bmatrix} = \frac{1}{C(s)} \begin{bmatrix} A(s) & \Delta_T \\ 1 & D(s) \end{bmatrix}, \quad (3.26)$$

where $\Delta_T = A(s)D(s) - B(s)C(s) = \pm 1$ for the reciprocal and anti-reciprocal systems respectively. This is best understood in term of Eq. 3.21. The off-diagonal coefficients $z_{12}(s)$ and $z_{21}(s)$ are defined as

$$z_{12}(s) = \left. \frac{\Phi_i}{U_l} \right|_{I_i=0} \quad z_{21}(s) = \left. \frac{F_l}{I_i} \right|_{U_l=0}$$

2380 The these off-diagonal elements are equal [$z_{12}(s) = z_{21}(s)$] the system is said to obey *Rayleigh reci-*
 2381 *procity*. If they are opposite in sign [$z_{12}(s) = -z_{21}(s)$], the system is said to be *anti-reciprocal*. If
 2382 a network has neither of the reciprocal or anti-reciprocal characteristics, then we denote it as *non-*
 2383 *reciprocal* (McMillan, 1946). The most comprehensive discussion of reciprocity, even to this day, is that
 2384 of Rayleigh (1896, Vol. I). The reciprocal case may be modeled as an ideal transformer (Van Valkenburg,
 2385 1964a) while for the anti-reciprocal case the generalized force and flow are swapped across the 2-port.
 2386 An electromagnetic transducer (e.g., a moving coil loudspeaker or electrical motor) is anti-reciprocal
 2387 (Kim and Allen, 2013; Beranek and Mellow, 2012), requiring a gyrator rather than a transformer, as
 2388 shown in Fig. 3.7.

2389 **Reversibility: P7** A second 2-port property is the *reversible/non-reversible* postulate. A reversible
 2390 system is invariant to the input and output impedances being swapped. This property is defined by
 2391 the input and output impedances being equal.

2392 Referring to Eq. 3.26, when the system is *reversible* $z_{11}(s) = z_{22}(s)$ or in terms of the transmission
 2393 matrix variables $\frac{A(s)}{C(s)} = \frac{D(s)}{C(s)}$ or simply $A(s) = D(s)$ assuming $C(s) \neq 0$.

2394 An example of a non-reversible system is a transformer where the turns ratio is not one. Also an
 2395 ideal operational amplifier (when the power is turned on) is non-reversible due to the large impedance

2396 difference between the input and output. Furthermore it is *active* (it has a power gain, due to the
 2397 current gain at constant voltage) (Van Valkenburg, 1964b).

2398 Generalizations of this lead to group theory, and *Noether's theorem*. These generalizations apply
 2399 to systems with many modes whereas quasistatics holds when operate below a cutoff frequency (Table
 2400 3.1), meaning that like the case of the transmission line, there are no propagating transverse modes.
 2401 While this assumption is never exact, it leads to highly accurate results because the non-propagating
 2402 evanescent transverse modes are attenuated over a short distance, and thus, in practice, may be ignored
 2403 (Montgomery et al., 1948; Schwinger and Saxon, 1968, Chap. 9-11).

2404 We extend the Carlin and Giordano postulate set to include (P7) Reversibility, which was refined by
 2405 Van Valkenburg (1964a). To satisfy the reversibility condition, the diagonal components in a system's
 2406 impedance matrix must be equal. In other words, the input force and the flow are proportional to the
 2407 output force and flow, respectively (i.e., $Z_e = z_m$).

2408 **Spatial invariant: P8** The characteristic impedance and wave number $\kappa(s, x)$ may be strongly
 2409 frequency and/or spatially dependent, or even be negative over some limited frequency ranges. Due to
 2410 *causality*, the concept of a negative group velocity must be restricted to a limited bandwidth (Brillouin,
 2411 1960). As is made clear by Einstein's theory of relativity, all materials must be strictly causal (P1),
 2412 a view that must therefore apply to acoustics, but at a very different time scale. We first discuss
 2413 generalized postulates, expanding on those of Carlin and Giordano.

2414 **The QS constraint: P9** When a system is described by the wave equation, delay is introduced
 2415 between two points in space, which depends on the wave speed. When the wavelength is large compared
 2416 to the delay, one may successfully apply the *quasistatic approximation*. This method has wide-spread
 2417 application, and is frequency used without mention of the assumption. This can lead to confusion,
 2418 since the limitations of the approximation may not be appreciated. An example is the use of QS in
 2419 Quantum Mechanics. The QS approximation has wide spread use when the signals may be accurately
 2420 approximated by a band-limited signal. Examples include KCL, KVL, wave guides, transmission lines,
 2421 and most importantly, impedance. The QS property is not mentioned in the six postulates of Carlin
 2422 and Giordano (1964), thus they need to be extended in some fundamental ways.

2423 When the dimensions of a cellular structure in the material are much less than the wavelength, can
 2424 the QS approximation be valid. This effect can be viewed as a *mode filter* that suppresses unwanted (or
 2425 conversely enhances the desired) modes (Ramo et al., 1965). Qs may be applied to a 3 dimensional
 2426 specification, as in a semiconductor lattice. But such applications fall outside the scope of this text
 2427 (Schwinger and Saxon, 1968).

2428 Although I have never seen the point discussed in the literature, the QS approximation is applied
 2429 when defining Green's theorem. For example, Gauss's Law is not true when the volume of the container
 2430 violates QS, since changes in the distribution of the charge have not reached the boundary, when doing
 2431 the integral. Thus such integral relationships assume that the system is in quasi steady-state (i.e., that
 2432 QS holds).

Table 3.1: There are several ways of indicating the quasi-static (QS) approximation. For network theory there is only one lattice constant a , which must be much less than the wavelength (wavelength constraint). These three constraints are not equivalent when the object may be a larger structured medium, spanning many wavelengths, but with a cell structure size much less than the wavelength. For example, each cell could be a Helmholtz resonator, or an electromagnetic transducer (i.e., an earphone).

Measure	Domain
$ka < 1$	Wavenumber constraint
$\lambda > 2\pi a$	Wavelength constraint
$f_c < c/2\pi a$	Bandwidth constraint

2433 Formally, QS is defined as $ka < 1$ where $k = 2\pi/\lambda = \omega/c$ and a is the cellular dimension or the size
2434 of the object (k and a can be vectors). Schelkunoff may have been the first to formalize this concept
2435 (Schelkunoff, 1943) (but not the first to use it, as exemplified by the Helmholtz resonator). George
2436 Ashley Campbell was the first to use the concept in the important application of a wave-filter, some
2437 30 years before Schelkunoff (Campbell, 1903). These two men were 40 years apart, and both worked
2438 for the telephone company (after 1929, called AT&T Bell Labs) (Fagen, 1975).

2439 There are alternative definitions of the QS approximation, depending on the geometrical cell struc-
2440 ture. The alternatives are outlined in Table 3.1.

2441 Summary

2442 A transducer converts between modalities. We propose the general definition of the nine system
2443 postulates, that include all transduction modalities, such as electrical, mechanical, and acoustical. It
2444 is necessary to generalize the concept of the QS approximation (P9) to allow for guided waves.

2445 Given the combination of the important QS approximation, along with these space-time, linearity,
2446 and reciprocity properties, a rigorous definition and characterization a system can thus be established.
2447 It is based on a taxonomy of such materials, formulated in terms of material and physical properties
2448 and in terms of extended network postulates.

2460 4.1 Week 8

2461 4.1.1 Lec 23 Newton and early calculus & the Bernoulli Family

2462 Newton and Calculus

2463 Bernoulli family

2464 Euler standard periodic (circular) function package

2465 The period of analytic discovery:

2466 Coming out of the dark ages, from algebra, to analytic geometry, to calculus.

2467 Starting with real analytic functions by Euler, we move to complex analytic functions with Cauchy.

2468 Integration in the complex plane is finally conquered.

Lect DE 25.9 Stream 3: ∞ and Sets

25.9.1

The development of real representations proceeded at a deadly-slow pace:

- *Real numbers* \mathbb{R} : Pythagoras knew of irrational numbers ($\sqrt{2}$)
- *Complex numbers* \mathbb{C} : 1572 “Bombelli is regarded as the inventor of complex numbers . . . ” <http://www-history.mcs.st-andrews.ac.uk/Biographies/Bombelli.html> http://en.wikipedia.org/wiki/Rafael_Bombelli & p. 258
- *Power Series*: Gregory-Newton interpolation formula c1670, p. 175
- Point at infinity and the Riemann sphere 1851
- Analytic functions p. 267 c1800; Impedance $Z(s)$ 1893

2469

Stream 3 Infinity

- Infinity ∞ was not “understood” until 19th CE
- ∞ is best defined in terms of a limit
- Limits are critical when defining calculus
- Set theory is the key to understanding Limits
- Open vs close sets determine when a limit exists (or not)
- Thus, to fully understand limits, one needs to understand set theory
- Related is the convergence of a series
- Every convergent series has a *Region of Convergence* (ROC)
- When the ROC is Complex:
 - Example of $\frac{1}{1-x}$ vs. $\frac{1}{i-x}$: The ROC is 1 for both cases
 - Why?
 - The case of the Heaviside step function $u(t)$ & the Fourier Transform

2470

Irrational numbers and limits (Ch. 4)

- How are irrational numbers interleaved with the integers?
- Between n and $2n$ there is always an irrational number:

Chebyshev said, and I say it again. There is always a prime between n and $2n$. -p. 585₂

2471

- *Prime number theorem*: The number of of primes is approximately(the density of primes is $\rho_{\pi}(n) \propto 1/\ln(n)$).
- The number of primes less than n is n times the density, or

$$N(n) = n/\ln(n).$$

- The formula for *entropy* is $\mathcal{H} = -\sum_n p_n \log p_n$.
Could there be some hidden relationship lurking here?

Stream 3: ∞ and Sets

25.9.2

- Understanding ∞ has been a primary goals since Euclid
- The Riemann sphere solves this fundamental problem
- The point at ∞ simply “another point” on the Riemann sphere

2472

2473 **Open vs. closed sets****Influence of open vs. closed set****7.3.6**

2474

- Important example: LT vs. FT step function: Dirac step vs Fourier step:
- $u(t) \leftrightarrow \frac{1}{s}$ vs. $\tilde{u}(t) \leftrightarrow \pi\delta(\omega) + \frac{1}{j\omega}$

2475

WEEK 9**23.9.0**

2476

2477

Week 9 Monday

2478

L 24 Power series and integration of functions (ROC)

2479

Fundamental Theorem of calculus (Leibniz theorem of integration)

2480

 $1/(1-x) = \sum_{k=0}^{\infty} x^k$ with $x \in \mathbb{R}$

2481

L 25 Integration in the complex plane: Three theorems

2482

Integration of $1/s$ on the unit circle, and on a unit circle centered about $s = 1 + i$.

2483

2484

L 26 Cauchy-Riemann conditions

2485

Real and imaginary parts of analytic functions obey Laplace's equation.

2486

Infinite power Series and analytic function theory; ROC

2487

2488

4.2 Week 9

2489

4.2.1 Lec 24 Power series and complex analytic functions

2490

L 24: Power series and complex analytic function

2492

L 25: Integration in the complex plane; Infinite power Series and analytic function theory; ROC

2493

Real and imaginary parts of analytic functions obey Laplace's equation.

2494

Colorized plots of analytic functions. How to read the plots and what they tell us?

2495

4.2.3 Lec 26 Cauchy Riemann conditions: Complex-analytic functions

2496

L 26: Cauchy Riemann conditions: Complex-analytic functions

2497

WEEK 10**26.10.0**

2498

2499

L 27 Differentiation in the complex plane: Fundamental Thm of complex calculus (FTCC);

2500

Complex Analytic functions; ROC in the complex plane

2501

 $Z(s) = R(s) + jX(s)$: real and imag parts obey Laplace's Equation

2502

Basic equations of mathematical Physics: Wave equation, Diffusion equation, Laplace's Equation

2503

Motivation: Dispersion relation for the wave equation $\kappa \cdot \kappa = s^2/c_0^2$

2504 L 28 Three Fundamental theorems of complex integral calculus
 2505 $\int_0^z = F(\zeta)d\zeta = F(z) - F(0)$: $dZ(s)/ds$ independent of direction
 2506 Integration in the complex plane; Integrals independent of limits
 2507 Cauchy-Riemann conditions

2508 L 29 Inverse Laplace transform
 2509 Inverse Laplace transform: Poles and Residue expansions;
 2510 Application of the Fundamental Thm of Complex Calculus
 2511 The Inverse Laplace Transform (ILT); poles and the Residue expansion: The case for causality
 2512 ROC as a function of the sign of time in e^{st} (How does causality come into play?)
 2513 Examples.

2514 4.3 Integration and differentiation in the complex plane

2515 4.3.1 Lec 27 Differentiation in the complex plane

2516 L 27: Differentiation in the complex plane: CR conditions?
 2517 Motivation: Inverse Laplace transform
 2518 ROC in the complex plane
 2519 Basic equations of mathematical Physics: Wave equation, Diffusion equation, Laplace's Equation
 2520 Motivation: Dispersion relation for the wave equation $\kappa \cdot \kappa = s^2/c_0^2$

2521 4.3.2 Lec 28 Three complex Integral Theorems

2522 L 28: Integration in the complex plane: Basic definitions of Three theorems
 2523 Integration of $1/s$ on the unit circle, and on a unit circle centered about $s = 1 + i$.
 2524
 2525 Moved from Lec 3 (page 31)

2526 **Set Theory:** Set theory is a topic that can be inadequately addressed in the undergraduate Engi-
 2527 neering and Physics curriculum, and is relatively young to mathematics. The set that a number is
 2528 drawn from is crucially important when taking limits.

2529 4.3.3 Lec 29 Inverse Laplace Transform

2530 L 29: Inverse Laplace transform: Poles and Residue expansions;
 2531 Application of the Fundamental Thm of Complex Calculus
 2532 Examples.

Stream 3: Infinity and irrational numbers Ch 4

2.1.6

- Limit points, open vs. closed sets are fundamental to modern mathematics
- These ideas first appeared with the discovery of $\sqrt{2}$, and \sqrt{n} https://en.wikipedia.org/wiki/Spiral_of_Theodorus and related constructions (factoring the square, Pell's Eq. p. 44)

2533 Infinity and irrational \mathbb{Q} numbers

The fundamental theorem of calculus

2.1.7

Let $A(x)$ be the area under $f(x)$. Then

$$\begin{aligned}\frac{d}{dx}A(x) &= \frac{d}{dx} \int f(\eta)d\eta \\ &= \lim_{\delta \rightarrow 0} \frac{A(x + \delta) - A(x)}{\delta}\end{aligned}$$

and/or

$$A(b) - A(a) = \int_a^b f(\eta)d\eta$$

- Stream 3 is about limits
- Integration and differentiation (Calculus) depend on limits
- Limits are built on open vs. closed sets

WEEK 11

30.11.0

2534

2535

2536 L 30 Inverse Laplace transform & Cauchy Residue Theorem

2537 L 31 Case for causality Closing the contour as $s \rightarrow \infty$; Role of $\Re st$ 2538 **DE-3**

2539 L 32 Properties of the LT:

2540 1) Modulation, 2) Translation, 3) convolution, 4) periodic functions

2567 4.5.2 Lec 34 The Riemann Zeta function $\zeta(s)$

- 2568 L34: Euler's vs. Riemann's Zeta function $\zeta(s)$: Poles at the primes
 2569 colored plot of $\zeta(s)$
 2570 ??Sterling's formula??

Table 4.1: Physical meaning of each factor of $\zeta(s)$

4.2.7

- Series expansion

$$\frac{1}{1-x} = 1 + x + x^2 + x^3 + \dots \quad \text{ROC: } |x| < 1$$

- If time T is a positive delay, then from the Laplace transform

$$\delta(t-T) \leftrightarrow \int_0^{\infty} \delta(t-T)e^{st} dt = e^{-sT}$$

- Each factor of $\zeta(s)$ is an ∞ sum of delays
- For example for $\pi_1 = 2$, ($T = \ln(2)$, thus $2^{-2} = e^{-s \ln 2}$)

$$\sum_n \delta(t-nT) \leftrightarrow \frac{1}{1-2^{-s}} = 1 + e^{-sT} + e^{-s2T} + \dots$$

Table 4.1: Each prime number defines a delay $T_k = \ln(\pi_k)$, which in turn defines a pole in the complex s plane. The series expansion of this pole is a train of delta functions that are one-sided periodic in the delta T . Thus each factor in the $\zeta(s)$ function defines a pole, having an incommensurate delay, since each pole is defined by a unique prime. Following this simple logic, we may interpret $\zeta(s)$ as being the Laplace transform of $Zeta(t)$, the cascade of quasi-periodic impulse responses, each with a recursive delay, determined by a prime. Note that 48100 = 10 · (2 · 5 · 13 · 37) is the sampling frequency [Hz] of modern CD players. This corresponds to the 20th harmonic of the US line frequency (60 [Hz]).^b

^asince $\text{gcd}(48100, 60) = 20$ and $\text{gcd}(48100, 50) = 50$.

^bsince $\text{gcd}(48100, 60) = 20$ and $\text{gcd}(48100, 50) = 50$.

2571 Riemann Zeta Function $\zeta(s)$

This very important analytic function is the credible argument for true deeper understanding of the power to the analytic function. Just like the Pythagorean theorem is important to all mathematics,

the zeta function is important to analysis, with many streams of analysis emanating from this form. For example the analytic Gamma function $\Gamma(s)$ is a generalization of the factorial by the relationship

$$n! = \Gamma(s - 1).$$

Another important relationship is

$$\sum_{k=n}^{\infty} k = nu_n = u_n \star u_n$$

where the \star represents convolution. If this is treated in the frequency domain then we obtain z-transforms of a very simple second-order pole¹

$$nu_n \leftrightarrow \frac{2}{(z-1)^2}.$$

This follows from the geometric series

$$\frac{1}{1-z} = \sum_n z^n$$

2572 with $z = e^s$, and the definition of convolution.

The Laplace transform does not require that the series converge, rather that the series have a region of convergence that is properly specified. Thus the non-convergent series nu_n is perfectly well defined, just like

$$tu(t) = u(t) \star u(t) \leftrightarrow \frac{1!}{s^2}$$

is well defined, in the Laplace transform sense. More generally

$$t^n u(t) \leftrightarrow \frac{n!}{s^{n+1}}.$$

From this easily understood relationship we can begin to understand $\Gamma(s)$, as the analytic extension of the factorial. Its definition is simply related to the inverse Laplace transform, which is an integral. But to go there we must be able to think in the complex frequency domain. In fact we have the very simple definition for $\Gamma(p)$ with $p \in \mathbb{C}$

$$t^{p-1} u(t) \leftrightarrow \frac{\Gamma(p)}{s^p}$$

2573 which totally explains $\Gamma(p)$. Thinking in the time domain is crucial for my understanding.

2574 **An example is a digital filter, which is linear. Such a system is shown in Fig. 4.3, where the two**
 2575 **functions are second order digital filters. The input signal $x[n]$ enters from the left, is filtered by the**
 2576 **first filter, producing output $y[n]$. This is then filtered again by the filter in the second box to produce**
 2577 **signal $z[n]$. For this simple case of two linear filters the operation *commute*.**

2578 4.5.3 Lec 35 Exam III

2579 L 35: Exam III

2580 Thanksgiving Holiday 11/19–11/27 2016

¹Need to verify the exact form of these relationships, not work from memory

Riemann Zeta Function $\zeta(s)$

4.2.5

- Integers appear as the “roots” (aka eigenmodes) of $\zeta(s)$
- Basic properties ($s = \sigma + i\omega$)

$$\zeta(s) \equiv \sum_1^{\infty} \frac{1}{n^s} \quad \sigma = \Re(s) > 0$$

– What is the region of convergence (ROC)?

- The amazing Euler-Riemann Product formula (Stillwell, 2010, Sect. 10.7:)

$$\begin{aligned} \zeta(s) &= \prod_k \frac{1}{1 - \pi_k^{-s}} = \prod_k \frac{1}{1 - \left(\frac{1}{\pi_k}\right)^s} = \prod_k \frac{1}{1 - \frac{1}{\pi_k^s}} \\ &= \frac{1}{1 - 2^{-s}} \cdot \frac{1}{1 - 3^{-s}} \cdot \frac{1}{1 - 5^{-s}} \cdot \frac{1}{1 - 7^{-s}} \cdots \frac{1}{1 - \pi_n^{-s}} \cdots \end{aligned}$$

- Euler c1750 assumed $s \subset \mathbb{R}$. Riemann c1850 extended $s \subset \mathbb{C}$

Figure 4.1: The zeta function arguably the most important of the special functions of analysis because it connects the primes to analytic function theory in a fundamental way.

Plot of $\angle\zeta(s)$

4.2.6

Angle of Riemann Zeta function $\angle\zeta(z)$ as a function of complex z

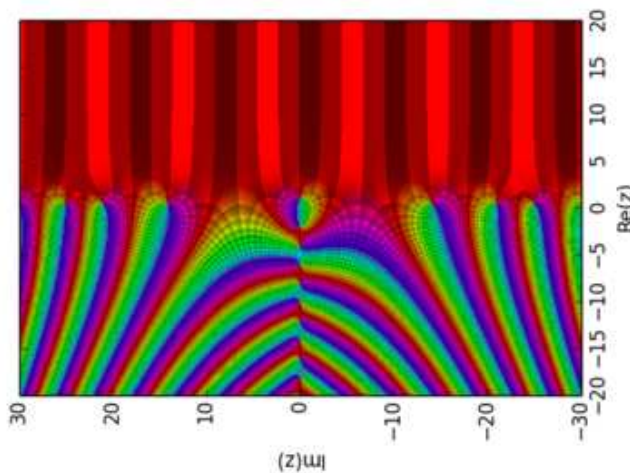

Figure 4.2: $\angle\zeta(z)$: Red $\Rightarrow \angle\zeta(z) < \pm\pi/2$

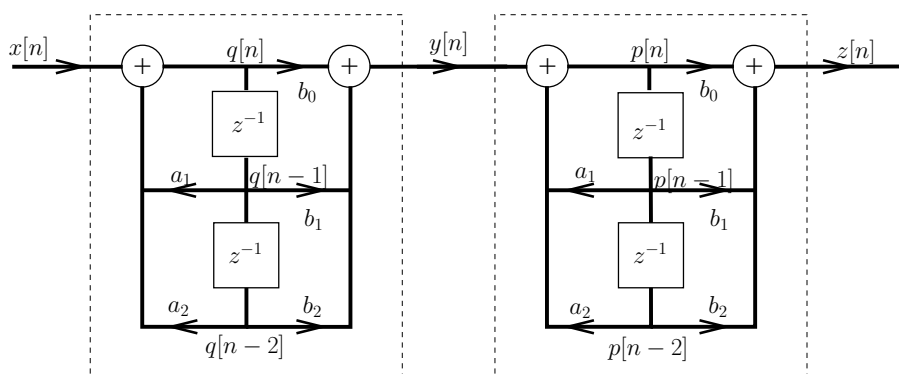

Figure 4.3: Example of a signal flow diagram for the composition of signals $z = g \circ f(x)$ with $y = f(x)$ and $z = g(y)$.

2617 5.3.1 Lec 39 Geometry of Gradient, divergence and curl vector operators

2618 Geometry of Gradient, divergence and curl vector operators

Lec 39: Review of vector field calculus

39.14.2

- Review of last few lectures: Basic definitions
 - *Field*: i.e., Scalar & vector fields are functions of more than one variable
 - “Del:” $\nabla \equiv [\partial_x, \partial_y, \partial_z]^T$
 - Gradient: $\nabla\phi(x, y, z) \equiv [\partial_x\phi, \partial_y\phi, \partial_z\phi]^T$
- *Helmholtz Theorem*:
 2619 Every vector field $\mathbf{V}(x, y, z)$ may be uniquely decomposed into *compressible* & *rotational* parts

$$\mathbf{V}(x, y, z) = -\nabla\phi(x, y, z) + \nabla \times \mathbf{A}(x, y, z)$$
- Scalar part $\nabla\phi$ is *compressible* ($\nabla\phi = 0$ is *incompressible*)
- Vector part $\nabla \times \mathbf{A}$ is *rotational* ($\nabla \times \mathbf{A} = 0$ is *irrotational*)
- Key vector identities: $\nabla \times \nabla\phi = 0$; $\nabla \cdot \nabla \times \mathbf{A} = 0$
- Definitions of Divergence, Curl & Maxwell's Eqs;
- Closure: Fundamental Theorems of Integral Calculus

Name	Input	Output	Operator
Gradient	Scalar	Vector	$-\nabla()$
Divergence	Vector	Scalar	$\nabla \cdot ()$
Curl	Vector	Vector	$\nabla \times ()$

Table 5.1: *The three vector operators manipulate scalar and vector fields, as indicated here. The gradient converts scalar fields into vector fields. The divergence eats vector fields and outputs scalar fields. Finally the curl takes vector fields into vector fields.*

2620 **Gradient****Gradient:** $\mathbf{E} = \nabla\phi(x, y, z)$ **39.14.3**

- Definition: $\mathbb{R}^1 \xrightarrow{\nabla} \mathbb{R}^3$

$$\mathbf{E}(x, y, z) = [\partial_x, \partial_y, \partial_z]^T \phi(x, y, z) = \left[\frac{\partial\phi}{\partial x}, \frac{\partial\phi}{\partial y}, \frac{\partial\phi}{\partial z} \right]_{x,y,z}^T$$

2621

- $\mathbf{E} \perp$ plane tangent at $\phi(x, y, z) = \phi(x_0, y_0, z_0)$
- Unit vector in direction of \mathbf{E} is $\hat{\mathbf{n}} = \frac{\mathbf{E}}{\|\mathbf{E}\|}$, along *isocline*
- Basic definition

$$\nabla\phi(x, y, z) \equiv \lim_{|\mathcal{S}| \rightarrow 0} \left\{ \frac{\iiint_{\mathcal{S}} \phi(x, y, z) \hat{\mathbf{n}} dA}{|\mathcal{S}|} \right\}$$

$\hat{\mathbf{n}}$ is a unit vector in the direction of the gradient
 \mathcal{S} is the surface area centered at (x, y, z)

2622 **Divergence****Divergence:** $\nabla \cdot \mathbf{D} = \rho$ **39.14.4a**

- Definition: $\mathbb{R}^3 \xrightarrow{\nabla \cdot} \mathbb{R}^1$

$$\nabla \cdot \mathbf{D} \equiv [\partial_x, \partial_y, \partial_z] \cdot \mathbf{D} = \left[\frac{\partial D_x}{\partial x} + \frac{\partial D_y}{\partial y} + \frac{\partial D_z}{\partial z} \right] = \rho(x, y, z)$$

- Examples:

2623

- Voltage about a point charge Q [SI Units of Coulombs]

$$\phi(x, y, z) = \frac{Q}{\epsilon_0 \sqrt{x^2 + y^2 + z^2}} = \frac{Q}{\epsilon_0 R}$$

ϕ [Volts]; Q [C]; Free space ϵ_0 *permittivity* (μ_0 *permeability*)

- *Electric Displacement* (flux density) around a point charge ($\mathbf{D} = \epsilon_0 \mathbf{E}$)

$$\mathbf{D} \equiv -\nabla\phi(R) = -Q\nabla \left\{ \frac{1}{R} \right\} = -Q\delta(R)$$

Divergence: The integral definition**39.14.4b**

- Surface integral definition of *incompressible* vector field

2624

$$\nabla \cdot \mathbf{D} \equiv \lim_{|\mathcal{V}| \rightarrow 0} \left\{ \frac{\iint_{\mathcal{S}} \mathbf{D} \cdot \hat{\mathbf{n}} dA}{|\mathcal{V}|} \right\} = \rho(x, y, z)$$

\mathcal{S} must be a closed surface

$\hat{\mathbf{n}}$ is the unit vector in the direction of the gradient

- $\hat{\mathbf{n}} \cdot \mathbf{D} \perp$ surface differential dA

Divergence: Gauss' Law

39.14.4c

- General case of a *Compressible* vector field
- Volume integral over charge density $\rho(x, y, z)$ is total charge enclosed Q_{enc}

2625

$$\iiint_{\mathcal{V}} \nabla \cdot \mathbf{D} dV = \iint_{\mathcal{S}} \mathbf{D} \cdot \hat{\mathbf{n}} dA = Q_{enc}$$

- Examples
 - When the vector field is *incompressible*
 - * $\rho(x, y, z) = 0$ [C/m³] over enclosed volume
 - * Surface integral is zero ($Q_{enc} = 0$)
 - Unit point charge: $D = \delta(R)$ [C/m²]

2626 **Curl**

$$\text{Curl: } \nabla \times \mathbf{H} = \mathbf{I} \text{ [amps/m}^2\text{]}$$

39.14.5a

- Definition: $\mathbb{R}^3 \xrightarrow{\nabla \times} \mathbb{R}^3$

2627

$$\nabla \times \mathbf{H} \equiv \begin{vmatrix} \hat{x} & \hat{y} & \hat{z} \\ \partial_x & \partial_y & \partial_z \\ H_x & H_y & H_z \end{vmatrix} = \mathbf{I}$$

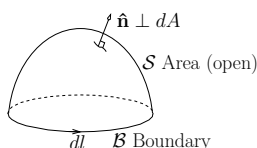

- Examples:
 - Maxwell's equations: $\nabla \times \mathbf{E} = -\dot{\mathbf{B}}$, $\nabla \times \mathbf{H} = \sigma \mathbf{E} + \dot{\mathbf{D}}$,
 - $\mathbf{H} = -y\hat{x} + x\hat{y}$ then $\nabla \times \mathbf{H} = 2\hat{z}$ constant *irrotational*
 - $\mathbf{H} = 0\hat{x} + 0\hat{y} + z^2\hat{z}$ then $\nabla \times \mathbf{H} = \mathbf{0}$ is *irrotational*

2628 **Stokes' Law**

$$\text{Curl: Stokes Law}$$

39.14.5b

- Surface integral definition of $\nabla \times \mathbf{H} = \mathbf{I}$ ($\mathbf{I} \perp$ rotation plane of \mathbf{H})

2629

$$\nabla \times \mathbf{H} \equiv \lim_{|\mathcal{S}| \rightarrow 0} \left\{ \frac{\iint_{\mathcal{S}} \hat{\mathbf{n}} \times \mathbf{H} dA}{|\mathcal{S}|} \right\} \quad (5.1)$$

$$\mathcal{I}_{enc} = \iint (\nabla \times \mathbf{H}) \cdot \hat{\mathbf{n}} dA = \oint_{\mathcal{B}} \mathbf{H} \cdot d\mathbf{l} \quad (5.2)$$

- Eq. (1): \mathcal{S} must be an *open surface* with closed boundary \mathcal{B}
 $\hat{\mathbf{n}}$ is the unit vector \perp to dA
 $\mathbf{H} \times \hat{\mathbf{n}} \in$ Tangent plane of A (i.e., $\perp \hat{\mathbf{n}}$)
- Eq. (2): Stokes Law: Line integral of \mathbf{H} along \mathcal{B} is total current \mathcal{I}_{enc}

2630 **5.3.2 Lec: 40 Introduction to Maxwell's Equation**

2661 **Properties****Closure: Properties of fields of Maxwell's Equations**

39.14.6

The variables have the following names and defining equations:

Symbol	Equation	Name	Units
\mathbf{E}	$\nabla \times \mathbf{E} = -\dot{\mathbf{B}}$	Electric Field strength	[Volts/m]
\mathbf{D}	$\nabla \cdot \mathbf{D} = \rho$	Electric Displacement (flux density)	[Col/m ²]
\mathbf{H}	$\nabla \times \mathbf{H} = \dot{\mathbf{D}}$	Magnetic Field strength	[Amps/m]
\mathbf{B}	$\nabla \cdot \mathbf{B} = 0$	Magnetic Induction (flux density)	[Weber/m ²]

In vacuo $\mathbf{B} = \mu_0 \mathbf{H}$, $\mathbf{D} = \epsilon_0 \mathbf{E}$, $c = \frac{1}{\sqrt{\mu_0 \epsilon_0}}$ [m/s], $r_0 = \sqrt{\frac{\mu_0}{\epsilon_0}} = 377$ [Ω].

2663 **Vector field properties****Closure: Summary of vector field properties**

39.14.7

- Notation: $\mathbf{v}(x, y, z) = -\nabla\phi(x, y, z) + \nabla \times \mathbf{w}(x, y, z)$
- Vector identities: $\nabla \times \nabla\phi = 0$; $\nabla \cdot \nabla \times \mathbf{w} = 0$

Field type	Generator:	Test (on \mathbf{v}):
Irrotational	$\mathbf{v} = \nabla\phi$	$\nabla \times \mathbf{v} = 0$
Rotational	$\mathbf{v} = \nabla \times \mathbf{w}$	$\nabla \times \mathbf{v} = \mathbf{J}$
Incompressible	$\mathbf{v} = \nabla \times \mathbf{w}$	$\nabla \cdot \mathbf{v} = 0$
Compressible	$\mathbf{v} = \nabla\phi$	$\nabla \cdot \mathbf{v} = \rho$

- Source density terms: Current: $\mathbf{J}(x, y, z)$, Charge: $\rho(x, y, z)$
 - Examples: $\nabla \times \mathbf{H} = \dot{\mathbf{D}}(x, y, z)$, $\nabla \cdot \mathbf{D} = \rho(x, y, z)$

2665 **Fundamental Theorem of integral Calculus****Closure: Fundamental Theorems of integral calculus**

39.14.8

1. $f(x) \in \mathbb{R}$ (Leibniz Integral Rule): $F(x) = F(a) + \int_a^x f(x)dx$
2. $f(s) \in \mathbb{C}$ (Cauchy's formula): $F(s) = F(a) + \int_a^s f(\zeta)d\zeta$
 –When integral is independent of path, $F(s) \in \mathbb{C}$ obeys CR conditions
 –Contour integration inverts causal Laplace transforms
3. $\mathbf{F} \in \mathbb{R}^3$ (Helmholtz Formula): $\mathbf{F}(x, y, z) = -\nabla\phi(x, y, z) + \nabla \times \mathbf{A}(x, y, z)$
 –Decompose $\mathbf{F}(x, y, z)$ as *compressible* and *rotational*
4. Gauss' Law (Divergence Theorem): $Q_{enc} = \iiint \nabla \cdot \mathbf{D} dV = \iint_S \mathbf{D} \cdot \hat{\mathbf{n}} dA$
 –Surface integral describes enclosed compressible sources
5. Stokes' Law (Curl Theorem): $\mathcal{I}_{enc} = \iint (\nabla \times \mathbf{H}) \cdot \hat{\mathbf{n}} dA = \oint_{\mathcal{B}} \mathbf{H} \cdot d\mathbf{l}$
 –Boundary vector line integral describes enclosed rotational sources
6. Green's Theorem ... Two-port boundary conditions
 –*Reciprocity* property (*Theory of Sound*, Rayleigh, J.W.S., 1896)

Closure: Quasi-static (QS) approximation

39.14.9

- Definition: $ka \ll 1$ where a is the size of object, $\lambda = c/f$ wavelength
- This is equivalent to $a \ll \lambda$ or
- $\omega \ll c/a$ which is a low-frequency approximation
- The QS approximation is widely used, but infrequently identified.
- All *lumped parameter models* (inductors, capacitors) are based on QS approximation as the lead term in a Taylor series approximation.

Appendix A

Notation

A.1 Number systems

The notation used in this book is defined in this appendix so that it may be quickly accessed.¹ Where the definition is sketchy, Page numbers are provided where these concepts are fully explained, along with many other important and useful definitions. For example \mathbb{N} may be found on page 22.

A.1.1 Greek letters

The Greek letters used in this text include (at least) $\alpha, \beta, \gamma, \delta, \epsilon, \kappa, \rho, \xi, \omega, \sigma, \phi, \psi, \zeta$, and upper-case $\Gamma, \Xi, \Phi, \Psi, \Delta, \Omega$. Many of these imply a physical meaning. For example, ω is the radian frequency, ρ is typically a density. Φ, ϕ, Ψ, ψ are commonly used to indicate angles of a triangle. For those of you who know this, its obvious. But at some time in your life, you had to learn these conventions. They were not implanted at birth.

Likely you do not know all of these Greek letters. But they are so commonly used in mathematics, you need to recognize them. Some of them are pronounced in a way that you may not know. The symbol ξ is pronounced “c,” ζ is “zeta” and χ is “kye.” I must assume you know how to pronounce the others, which are more phonetic in English. One advantage of learning L^AT_EX is that all of these math symbols are built in, and thus easily learned, by using this powerful open-source math-oriented word-processing system.

A.1.2 Double-Bold notation

Table A.1 indicates the symbol followed by a page number and the name of the number type. For example \mathbb{N} stands for the infinite set of *counting numbers* $\{1, 2, 3, \dots\}$. From any counting number you may get the next one by adding 1.

Summary of various number types: Counting number (\mathbb{N}) are also know as the Cardinal numbers. The prime numbers (\mathbb{P}) cannot be further factored. The counter example of $-5 = -1 \cdot 5$ is questionable, as it could be included as a prime by a slight change in the definition. One may say that a real (\mathbb{R}) is a complex number (\mathbb{C}) with a zero imaginary part, thus real numbers are complex ($\mathbb{R} \subset \mathbb{C}$).

Note that $\mathbb{R} : \mathbb{I} \cup \mathbb{Q}, \mathbb{I} \perp \mathbb{Q}, \mathbb{Q} : \mathbb{Z} \cup \mathbb{F}$.

We say that a number is in the set with the notation $3 \in \mathbb{N} \in \mathbb{R}$, which is read as “3 is in the set of counting numbers, which in turn in the set of real numbers,” or in vernacular language “3 is a real counting number.”

The *cardinality* of a set is denoted by taking the absolute value (e.g., $|\mathbb{N}|$).

¹https://en.wikipedia.org/wiki/List_of_mathematical_symbols_by_subject#Definition_symbols

Table A.1: Double-bold notation for the types of numbers. (#) is a page number.

Symbol (p. #)	Genus	Examples	Counter Examples
N (22)	Counting	1,2,17,3, 10^{20}	0, -10, 5j
P (22)	Prime	2,17,3, 10^{20}	0, 1, 4, 3^2 , 12, -5
Z (22)	Integer	-1, 0, 17, 5j, -10^{20}	$1/2, \pi, \sqrt{5}$
Q (22)	Rational	2/1, 3/2, 1.5, 1.14	$\sqrt{2}, 3^{-1/3}, \pi$
F (22)	Fractional	1/2, 7/22	2/1, $1/\sqrt{2}$
I (23)	Irrational	$\sqrt{2}, 3^{-1/3}, \pi$	Vectors
R (23)	Reals	$\sqrt{2}, 3^{-1/3}, \pi$	$2\pi j$
C (115)	Complex	1, $\sqrt{2}j, 3^{-j/3}, \pi^j$	Vectors

A.2 Periodic functions

Any periodic function may be indicated using double-parentheses notation. This is sometimes known as modular arithmetic. For example function

$$f((t))_T = f(t) = f(t \pm kT),$$

is periodic on $t, T \in \mathbb{R}$ with a period of T and $k \in \mathbb{Z}$. This notation is useful when dealing with Fourier series of periodic functions.

When a discrete valued (e.g., time) sequence is periodic we use square brackets

$$f[[n]]_N = f[n] = f[n \pm kN],$$

with $n, k, N \in \mathbb{Z}$ and period N . This notation will be used with discrete-time signals that are periodic, such as the case of the DFT.

A.3 Vectors

Vectors are ordered sets of scalars. When we write them out, we use row notation, with the *transpose* symbol

$$[a, b, c]^T = \begin{bmatrix} a \\ b \\ c \end{bmatrix}.$$

Vectors are always columns. Row vectors are weights not vectors. A vector dot product is normally defined between weights and vectors, resulting in a real scalar. This is said to be a 3 *dimensional* vector. for example

$$\begin{bmatrix} 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = 1 + 2 + 3 = 6.$$

When the elements are complex, the transpose also takes the complex conjugate.

A.4 Matrices

Unfortunately when working with matrices, the role of the weights and vectors can change, depending on the context. A useful way to view a matrix is as a set of column vectors, weighted by the elements

of the column-vector of weights multiplied from the right. For example

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1M} \\ a_{21} & a_{22} & a_{32} & \cdots & a_{3M} \\ & & \ddots & & \\ a_{N1} & a_{N2} & a_{N3} & \cdots & a_{NM} \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ \cdots \\ w_M \end{bmatrix} = w_1 \begin{bmatrix} a_{11} \\ a_{21} \\ a_{21} \\ \cdots \\ a_{N1} \end{bmatrix} + w_2 \begin{bmatrix} a_{12} \\ a_{22} \\ a_{32} \\ \cdots \\ a_{N2} \end{bmatrix} \cdots w_M \begin{bmatrix} a_{1M} \\ a_{2M} \\ a_{3M} \\ \cdots \\ a_{NM} \end{bmatrix},$$

where the weights are $[w_1, w_2, \dots, w_M]^T$

Another way to view the matrix is a set of row vectors of weights, each of which re applied to the vector $[w_1, w_2, \dots, w_M]^T$.

The determinant of a matrix is denoted either as $\det \mathbf{A}$ or $|\mathbf{A}|$, as in the absolute value. The inverse of a square matrix is \mathbf{A}^{-1} or $\text{inv}\mathbf{A}$. If $|\mathbf{A}| = 0$, the inverse does not exist. $\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A}$.

Matlab’s notional convention for a row-vector is $[a, b, c]$ and a column-vector is $[a; b; c]$. A prime on a vector takes the complex conjugate transpose. To suppress the conjugation, place a period before the prime. The `:` argument converts the array into a column vector, without conjugation. A tacit notation in Matlab is that *vectors* are columns and the index to a vector is a row vector. Matlab defines the notation `1:4` as the “row-vector” $[1, 2, 3, 4]$, which is unfortunate as it leads users to assume that the default vector is a row. This can lead to serious confusion later, as Matlab’s default vector is a column. I have not found the above convention explicitly stated, and it took me years to figure this out for myself.

Units are SI; Angles in degrees `[deg]` unless otherwise noted. The units for π are always in radians `[rad]`. Ex: $\sin(\pi)$, e^{j90° , $e^{j\pi/2}$.

when writing a complex number we shall try to use $1j$ to indicate $\sqrt{-1}$. Matlab prefers this as well, as its explicit.

A.5 Differential equations vs. Polynomials

A polynomial has *degree* N defined by the largest power. A quadratic equation is degree 2, and a cubic has degree 3. We shall indicate a polynomial by the notation

$$P_N(z) = z^N + a_{N-1}z^{N-1} \cdots a_0.$$

Always normalize the polynomial so that $a_N = 1$. This will not change the roots, defined by Eq. 1.10 (p. 43). The coefficient on z^{N-1} is always the sum of the roots z_n ($a_{N-1} = \sum_n^N z_n$), and a_0 is always their product ($a_0 = \prod_n^N z_n$).

Differential equations have *order* (polynomials have degree). If a second order differential equation is Laplace transformed (Lec. 1.3.10, p. 59), one is left with a degree 2 polynomial. For example:

$$\frac{d^2}{dt^2}y(t) + b\frac{d}{dt}y(t) + cy(t) = \alpha \left(\frac{d}{dt}x(t) + \beta x(t) \right) \leftrightarrow \tag{A.1}$$

$$(s^2 + bs + c)Y(s) = \alpha(s + \beta)X(s). \tag{A.2}$$

$$\frac{Y(s)}{X(s)} = \alpha \frac{s + \beta}{s^2 + bs + c} \equiv H(s) \leftrightarrow h(t). \tag{A.3}$$

Using the same argument as for polynomials, the lead coefficient must always be 1. The coefficient $\alpha \in \mathbb{R}$ is called the *gain*. The complex variable s is the *Laplace frequency*.

The ratio of the output $Y(s)$ over the input $X(s)$ is called the system *transfer function* $H(s)$. When $H(s)$ is the ratio of two polynomials in s , the transfer function is said to be *bilinear*, since it is linear in both the input and output. The roots of the numerator are called the *zeros* and those of the denominator, the *poles*. The inverse Laplace transform of the transfer function is called the system *impulse response*, which describes the system’s output signal $y(t)$ for any given input signal $x(t)$, via convolution (i.e., $y(t) = h(t) \star x(t)$).

A.6 Residue expansions and the ROC

With the new tool of analytic functions came the concept of the *region of convergence* (ROC) that defines the regions in the complex plane where the infinite series is valid. In other words, the function $Z(s)$ and its analytic power series $\sum_0^\infty c_n s^n$, are equivalent over a region of s that lies within the ROC. When the series fails to converge, it no longer represents $Z(s)$. A helpful example is the series

$$\frac{1}{1+x^2} = \frac{1}{(1-xj)(1+xj)} = \frac{A}{1-xj} + \frac{B}{1+xj} = \frac{1}{2} \sum_{n=0}^{\infty} (+xj)^n + \frac{1}{2} \sum_{n=0}^{\infty} (-xj)^n,$$

which is valid for $|x| < 1$. At face value this function seems fine at $x = 1$, where it is equal to $1/2$. In fact the series fails to converge at precisely this value (the ROC is 1 for this example). Until one views x as complex, this behavior is not obvious.

A trivial analysis shows that $A = 1/2$ and $B = A$ since

$$1 = A(1+xj) + B(1-xj) = (A+Axj) + (B-Bxj) = A+B + (A-B)xj.$$

Appendix B

Linear algebra on 2x2 matrices

B.1 Gaussian elimination

Definitions:

1. *Scalar*: A number, e.g. $\{a, b, c, \alpha, \beta, \dots\} \in \{\mathbb{Z}, \mathbb{Q}, \mathbb{I}, \mathbb{R}, \mathbb{C}\}$
2. *Vector*: A quantity having direction as well as magnitude, often denoted by a bold-face letter with an arrow, \vec{x} . In matrix notation, this is typically represented as a single row $[x_1, x_2, x_3, \dots]$ or single column $[x_1, x_2, x_3 \dots]^T$ (where T indicates the transpose). In this class we will typically use column vectors. The vector may also be written out using unit vector notation to indicate direction. For example: $\vec{x}_{3 \times 1} = x_1\hat{x} + x_2\hat{y} + x_3\hat{z} = [x_1, x_2, x_3]^T$, where $\hat{x}, \hat{y}, \hat{z}$ are unit vectors in the x, y, z cartesian directions (here the vector's subscript 3×1 indicates its dimensions). The type of notation used may depend on the engineering problem you are solving.
3. *Matrix*: $A = [\vec{a}_1, \vec{a}_2, \vec{a}_3, \dots, \vec{a}_M]_{N \times M} = \{a_{n,m}\}_{N \times M}$, can be a non-square matrix if the number of elements in each of the vectors (N) is not equal to the number of vectors (M). When $M = N$, the matrix is square. It may be inverted if its determinant $|A| = \prod \lambda_k \neq 0$ (where λ_k are the eigenvalues).

We shall only work with 2×2 and 3×3 square matrices throughout this course.

4. *Linear system of equations*: $A\vec{x} = \vec{b}$ where \vec{x} and \vec{b} are vectors and matrix A is a square.
 - (a) *Inverse*: The solution of this system of equations may be found by finding the inverse $\vec{x} = A^{-1}\vec{b}$
 - (b) *Equivalence*: If two systems of equations $A_0\vec{x} = \vec{b}_0$ and $A_1\vec{x} = \vec{b}_1$ have the same solution (i.e., $\vec{x} = A_0^{-1}\vec{b}_0 = A_1^{-1}\vec{b}_1$), they are said to be equivalent.
 - (c) *Augmented matrix*: The first type of augmented matrix is defined by combining the matrix with the right-hand-side. For example, given the linear system of equations $A\vec{x} = \vec{y}$

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix},$$

then the augmented matrix is

$$A|y = \left[\begin{array}{cc|c} a & b & y_1 \\ c & d & y_2 \end{array} \right]$$

A second type of augmented matrix may be used for finding the inverse of a matrix (rather than solving a specific instance of linear equations $Ax = b$). In this case the augmented matrix is

$$A|I = \left[\begin{array}{cc|cc} a & b & 1 & 0 \\ c & d & 0 & 1 \end{array} \right]$$

Performing Gaussian elimination on this matrix, until the left side becomes the identity matrix, yields A^{-1} . This is because multiplying both sides by A^{-1} gives $A^{-1}A|A^{-1}I = I|A^{-1}$.

5. *Permutation matrix (P)*: A matrix that is equivalent to the identity matrix, but with scrambled rows (or columns). Such a matrix has the properties $\det(P) = \pm 1$ and $P^2 = I$. For the 2x2 case, there is only one permutation matrix:

$$P = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad P^2 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

A permutation matrix P swaps rows or columns of the matrix it operates on. For example, in the 2x2 case, pre-multiplication swaps the rows

$$PA = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} a & b \\ \alpha & \beta \end{bmatrix} = \begin{bmatrix} \alpha & \beta \\ a & b \end{bmatrix},$$

whereas post-multiplication swaps the *columns*

$$AP = \begin{bmatrix} a & b \\ \alpha & \beta \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} b & a \\ \beta & \alpha \end{bmatrix}$$

For the 3x3 case there are $3 \cdot 2 = 6$ such matrices, including the original 3x3 identity matrix (swap a row with the other 2, then swap the remaining two rows).

6. *Gaussian elimination (GE) matrices G_k* : There are 3 types of elementary row operations, which may be performed without fundamentally altering a system of equations (e.g. the resulting system of equations is *equivalent*). These operations are (1) swap rows (e.g. using a permutation matrix), (2) scale rows, or (3) perform addition/subtraction of two scaled rows. All such operations can be performed using matrices.

For lack of a better term, we'll describe these as 'gaussian elimination' or 'GE' matrices.¹ We will categorize any matrix that performs only elementary row operations (but any number of them) as a 'GE' matrix. Therefore, cascade of GE matrices is also a GE matrix.

Consider the GE matrix

$$G = \begin{bmatrix} 1 & 0 \\ 1 & -1 \end{bmatrix}$$

- (a) Pre-multiplication scales and adds the *rows*

$$GA = \begin{bmatrix} 1 & 0 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} a & b \\ \alpha & \beta \end{bmatrix} = \begin{bmatrix} a & b \\ a - \alpha & b - \beta \end{bmatrix}$$

The result is a Gaussian elimination operation.

- (b) Post-multiplication adds and scales *columns*.

$$AG = \begin{bmatrix} a & b \\ \alpha & \beta \end{bmatrix} \begin{bmatrix} 1 & 0 \\ -1 & 1 \end{bmatrix} = \begin{bmatrix} a - b & b \\ \alpha - \beta & \beta \end{bmatrix}$$

Here the second column is subtracted from the first, and placed in the first. The second column is untouched. **This operation is *not* a Gaussian elimination.** Therefore, to

¹The term 'elementary matrix' may also be used to refer to a matrix that performs an elementary row operation. Typically, each elementary matrix differs from the identity matrix by one single row operation. A cascade of elementary matrices could be used to perform Gaussian elimination.

put Gaussian elimination operations in matrix form, we form a cascade of **pre-multiply** matrices.

Here $\det(G) = 1$, $G^2 = I$, which won't always be true if we scale by a number greater than

1. For instance, if $G = \begin{bmatrix} 1 & 0 \\ m & 1 \end{bmatrix}$ (scale and add), then we have $\det(G) = 1$, $G^n = \begin{bmatrix} 1 & 0 \\ n \cdot m & 1 \end{bmatrix}$.

B.1.1 Problems

Find the solution to the following 3x3 matrix equation $Ax = b$ by Gaussian elimination. Show your intermediate steps. You can check your work at each step using Matlab.

$$\begin{bmatrix} 1 & 1 & -1 \\ 3 & 1 & 1 \\ 1 & -1 & 4 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 9 \\ 8 \end{bmatrix}.$$

1. Show (i.e., verify) that the first GE matrix G_1 , which zeros out all entries in the first column, is given by

$$G_1 = \begin{bmatrix} 1 & 0 & 0 \\ -3 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}$$

Identify the elementary row operations that this matrix performs. [See Lab manual for solutions.](#)

2. Find a second GE matrix, G_2 , to put G_1A in upper triangular form. Identify the elementary row operations that this matrix performs. [See Lab manual for solutions.](#)
3. Find a third GE matrix, G_3 , which scales each row so that its leading term is 1. Identify the elementary row operations that this matrix performs. [See Lab manual for solutions.](#)
4. Finally, find the last GE matrix, G_4 , that subtracts a scaled version of row 3 from row 2, and scaled versions of rows 2 and 3 from row 1, such that you are left with the identity matrix ($G_4G_3G_2G_1A = I$). [See Lab manual for solutions.](#)
5. Solve for $[x_1, x_2, x_3]^T$ using the augmented matrix format $G_4G_3G_2G_1[A|b]$ (where $[A|b]$ is the augmented matrix). Note that if you've performed the preceding steps correctly, $x = G_4G_3G_2G_1b$. [See Lab manual for solutions.](#)

B.2 Gaussian Elimination of a 2x2 matrix

We shall now apply Gaussian elimination to find the solution $[x_1, x_2]$ for the 2x2 matrix equation $Ax = y$ (Eq. 3.7, left). We assume to know $[a, b, c, d]$ and $[y_1, y_2]$. We wish to show that the intersection (solution) is given by the equation on the right.

Here we wish to prove that the left equation has an inverse given by the right equation:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \qquad \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

How to take inverse:

1) Swap the diagonal, 2) change the signs of the off-diagonal, and 3) divide by Δ .

B.2.1 Derivation of the inverse of a 2x2 matrix

1. Step 1: normalize the first column to 1.
2. Step 2: subtract the top equation from the lower.
3. Step 3: express result in terms of the determinate $\Delta = ad - bc$.

$$\begin{bmatrix} 1 & \frac{b}{a} \\ 1 & \frac{d}{c} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \frac{1}{a}y_1 \\ \frac{1}{c}y_2 \end{bmatrix} \quad \begin{bmatrix} 1 & \frac{b}{a} \\ 0 & \frac{d}{c} - \frac{b}{a} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \frac{1}{a} & 0 \\ -\frac{1}{a} & \frac{1}{c} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \quad \begin{bmatrix} 1 & \frac{b}{a} \\ 0 & \Delta \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \frac{1}{a} & 0 \\ -c & a \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

4. Step 4: These steps give the solution for x_2 : $x_2 = -\frac{c}{\Delta}y_1 + \frac{a}{\Delta}y_2$.
5. Step 5: Finally the top equation is solved for x_1 : $x_1 = \frac{1}{a}y_1 - \frac{b}{a}x_2 = x_1 = \frac{1}{a}y_1 - \frac{b}{a}\left[-\frac{c}{\Delta}y_1 + \frac{a}{\Delta}y_2\right]$.

In matrix format, in terms of the determinate $\Delta = ab - cd$ becomes:

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \frac{1}{a} - \frac{bc}{a\Delta} & \frac{b}{\Delta} \\ -\frac{c}{\Delta} & \frac{a}{\Delta} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \quad \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} \frac{\Delta-bc}{a} & -b \\ -c & a \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \quad \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}.$$

Summary: This is a lot of algebra, that is why it is essential you memorize the formula for the inverse.

Appendix C

Eigenvector analysis

Here we show how to compute the eigenvalues and eigenvectors for the 2x2 Pell matrix

$$\mathbf{A} = \begin{bmatrix} 1 & N \\ 1 & 1 \end{bmatrix}.$$

The analysis applies to any matrix, but since we are concentrated on Pell's equation, we shall use the Pell matrix, for $N = 2$. By using a specific matrix we can check all the equations below with Matlab, which I advise you to do.

The Matlab command `[E,D]=eig(A)` returns the eigenvector matrix \mathbf{E}

$$\mathbf{E} = [\mathbf{e}_+, \mathbf{e}_-] = \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 0.8165 & -0.8165 \\ 0.5774 & 0.5774 \end{bmatrix}$$

and the eigenvalue matrix Λ (Matlab's D)

$$\Lambda \equiv \begin{bmatrix} \lambda_+ & 0 \\ 0 & \lambda_- \end{bmatrix} = \begin{bmatrix} 1 + \sqrt{2} & 0 \\ 0 & 1 - \sqrt{2} \end{bmatrix} = \begin{bmatrix} 2.4142 & 0 \\ 0 & -0.4142 \end{bmatrix}.$$

The factor $\sqrt{3}$ on \mathbf{E} normalizes each eigenvector to 1 (i.e., The Matlab command `norm([sqrt(2), 1])` gives $\sqrt{3}$).

In the following discussion we show how to determine \mathbf{E} and D (i.e, Λ), given \mathbf{A} .

Calculating the eigenvalue matrix (Λ): The matrix equation for \mathbf{E} is

$$\mathbf{A}\mathbf{E} = \mathbf{E}\Lambda. \tag{C.1}$$

Pre-multiplying by \mathbf{E}^{-1} diagonalizes \mathbf{A} , given the *eigenvalue matrix* (D in Matlab)

$$\Lambda = \mathbf{E}^{-1}\mathbf{A}\mathbf{E}. \tag{C.2}$$

Post-multiplying by \mathbf{E}^{-1} recovers \mathbf{A}

$$\mathbf{A} = \mathbf{E}\Lambda\mathbf{E}^{-1}. \tag{C.3}$$

Matrix power formula: This last relation is the entire point of the eigenvector analysis, since it shows that any power of \mathbf{A} may be computed from powers of the eigen values. Specifically

$$\mathbf{A}^n = \mathbf{E}\Lambda^n\mathbf{E}^{-1}. \tag{C.4}$$

For example, $\mathbf{A}^2 = \mathbf{A}\mathbf{A} = \mathbf{E}\Lambda(\mathbf{E}^{-1}\mathbf{E})\Lambda\mathbf{E}^{-1} = \mathbf{E}\Lambda^2\mathbf{E}^{-1}$.

Equations C.1, C.2 and C.3 are the key to eigenvector analysis, and you need to memorize them. You will use them repeatedly throughout this course, and for a long time after it is over.

Showing that $\mathbf{A} - \lambda_{\pm}\mathbf{I}_2$ is singular: If we restrict Eq. C.1 to a single eigenvector (one of \mathbf{e}_{\pm}), along with the corresponding eigenvalue λ_{\pm} , we obtain a matrix equations

$$\mathbf{A}\mathbf{e}_{\pm} = \mathbf{e}_{\pm}\lambda_{\pm} = \lambda_{\pm}\mathbf{e}_{\pm}$$

Note the important swap in the order of \mathbf{e}_{\pm} and λ_{\pm} . Since λ_{\pm} is a scalar, this is legal (and critically important), since this allows us to remove (factored out) \mathbf{e}_{\pm}

$$(\mathbf{A} - \lambda_{\pm}\mathbf{I}_2)\mathbf{e}_{\pm} = 0. \quad (\text{C.5})$$

This means that the matrix $\mathbf{A} - \lambda_{\pm}\mathbf{I}_2$ must be singular, since when it operates on \mathbf{e}_{\pm} , which is not zero, it gives zero. It immediately follows that its determinant is zero (i.e., $|(\mathbf{A} - \lambda_{\pm}\mathbf{I}_2)| = 0$). This equation is used to uniquely determine the eigenvalues λ_{\pm} . Note the important difference between $\lambda_{\pm}\mathbf{I}_2$ and Λ (i.e., $|(A - \Lambda)| \neq 0$).

Calculating the eigenvalues λ_{\pm} : The eigenvalues λ_{\pm} of \mathbf{A} may be determined from $|(\mathbf{A} - \lambda_{\pm}\mathbf{I}_2)| = 0$

$$\begin{vmatrix} 1 - \lambda_{\pm} & N \\ 1 & 1 - \lambda_{\pm} \end{vmatrix} = (1 - \lambda_{\pm})^2 - N^2 = 0.$$

For our case of $N = 2$, $\lambda_{\pm} = (1 \pm \sqrt{2})$.¹

Calculating the eigenvectors \mathbf{e}_{\pm} : Once the eigenvalues have been determined, they are substitute them into Eq. C.5, which determines the eigenvectors $\mathbf{E} = [\mathbf{e}_+, \mathbf{e}_-]$, by solving

$$(\mathbf{A} - \lambda_{\pm})\mathbf{e}_{\pm} = \begin{bmatrix} 1 - \lambda_{\pm} & 2 \\ 1 & 1 - \lambda_{\pm} \end{bmatrix} \mathbf{e}_{\pm} = 0$$

where $1 - \lambda_{\pm} = 1 - (1 \pm \sqrt{2}) = \mp\sqrt{2}$.

Recall that Eq. C.5 is singular, because we are using an eigenvalue, and each eigenvector is pointing in a unique direction (This is why it is singular). You might respectively suggest that this equation has no solution. In some sense you would be correct. When we solve for \mathbf{e}_{\pm} , the two equations defined by Eq. C.5 *co-linear* (the two equations describe parallel lines). This follows from the fact that there is only one eigenvector for each eigenvalue.

Expecting trouble, yet proceeding to solve for $\mathbf{e}_+ = [e_1^+, e_2^+]^T$,

$$\begin{bmatrix} -\sqrt{2} & 2 \\ 1 & -\sqrt{2} \end{bmatrix} \begin{bmatrix} e_1^+ \\ e_2^+ \end{bmatrix} = 0$$

This gives two identical equations $-\sqrt{2}e_1^+ + 2e_2^+ = 0$ and $e_1^+ - \sqrt{2}e_2^+ = 0$. This is the price of an over-specified equation (the singular matrix is degenerate). The most we can determine is $\mathbf{e}_+ = c[-\sqrt{2}, 1]^T$, where c is a constant. We can determine eigenvector direction, but not its magnitude.

Following *exactly* the same procedure for λ_- , the equation for \mathbf{e}_- is

$$\begin{bmatrix} \sqrt{2} & 2 \\ 1 & \sqrt{2} \end{bmatrix} \begin{bmatrix} e_1^- \\ e_2^- \end{bmatrix} = 0$$

In this case the relation becomes $e_1^- + \sqrt{2}e_2^- = 0$, thus $\mathbf{e}_- = c[\sqrt{2}, 1]^T$ where c is a constant.

Normalization of the eigenvectors: The two constants may be determined by normalizing the eigenvectors to have unit length. Since we cannot determine the length, we set it to 1. In some sense the degeneracy is resolved by this normalization. Thus $c = 1/\sqrt{3}$, since

$$c^2 \left((\pm\sqrt{2})^2 + 1^2 \right) = 3c^2 = 1.$$

¹It is a convention to order the eigenvalues from largest to smallest.

Summary: Thus far we have shown

$$\mathbf{E} = [\mathbf{e}_+, \mathbf{e}_-] = \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix}$$

and

$$\Lambda = \begin{bmatrix} \lambda_+ & 0 \\ 0 & \lambda_- \end{bmatrix} = \begin{bmatrix} 1 + \sqrt{2} & 0 \\ 0 & 1 - \sqrt{2} \end{bmatrix}.$$

Verify that $\Lambda = \mathbf{E}^{-1}\mathbf{A}\mathbf{E}$: To find the inverse of \mathbf{E} , 1) swap the diagonal values, 2) change the sign of the off diagonals, and 3) divide by the determinant $\Delta = 2\sqrt{2}/\sqrt{3}$ (see Appendix B)

$$\mathbf{E}^{-1} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ -1 & \sqrt{2} \end{bmatrix} = \begin{bmatrix} 0.6124 & 0.866 \\ -0.6124 & 0.866 \end{bmatrix}.$$

By definition for any matrix $\mathbf{E}^{-1}\mathbf{E} = \mathbf{E}\mathbf{E}^{-1} = \mathbf{I}_2$. Taking the product gives

$$\mathbf{E}^{-1}\mathbf{E} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ -1 & \sqrt{2} \end{bmatrix} \cdot \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \mathbf{I}_2.$$

We wish to show that $\Lambda = \mathbf{E}^{-1}\mathbf{A}\mathbf{E}$

$$\begin{bmatrix} 1 + \sqrt{2} & 0 \\ 0 & 1 - \sqrt{2} \end{bmatrix} = \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ -1 & \sqrt{2} \end{bmatrix} \cdot \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} \cdot \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix},$$

which is best verified with Matlab.

Verify that $\mathbf{A} = \mathbf{E}\Lambda\mathbf{E}^{-1}$: We wish to show that

$$\begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix} = \frac{1}{\sqrt{3}} \begin{bmatrix} \sqrt{2} & -\sqrt{2} \\ 1 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 + \sqrt{2} & 0 \\ 0 & 1 - \sqrt{2} \end{bmatrix} \cdot \frac{\sqrt{3}}{2\sqrt{2}} \begin{bmatrix} 1 & \sqrt{2} \\ -1 & \sqrt{2} \end{bmatrix},$$

which is best verified with Matlab (or Octave).

I suggest that you verify $\mathbf{E}\Lambda \neq \Lambda\mathbf{E}$ and $\mathbf{A}\mathbf{E} = \mathbf{E}\Lambda$ with Matlab. Here is the Matlab program which does this:

```
A = [1 2; 1 1]; %define the matrix
[E,D] = eig(A); %compute the eigenvector and eigenvalue matrices
A*E-E*D %This should be $\approx 0$, within numerical error.
E*D-D*E %This is not zero
```

All the equations have been verified both with Matlab and Octave.

Appendix D

Solution to Pell's Equation (N=2)

Section 2.2.2 (p. 83) showed that the solution $[x_n, y_n]^T$ to Pell's equation, for $N = 2$, is given by powers of Eq. 1.4. To find an explicit formula for $[x_n, y_n]^T$, one must compute powers of

$$\mathbf{A} = 1j \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix}. \quad (\text{D.1})$$

We wish to find the solution to Pell's equation (Eq. 1.4), based on the recursive solution, Eq. 1.5 (p. 38). Thus we need is powers of A , that is A^n , which gives the a closed form expression for $[x_n, y_n]^T$. By the diagonalization of A , its powers are simply the powers of its eigenvalues. This diagonalization is called an *eigenvalue analysis*, a very general method rooted in linear algebra. This type of analysis allows us to find the solution to most of the linear the equations we encounter.

From Matlab with $N = 2$ the eigenvalues of Eq. D.1 are $\lambda_{\pm} \approx [2.4142j, -0.4142j]$ (i.e., $\lambda_{\pm} = 1j(1 \pm \sqrt{2})$). The final solution to Eq. D.1 is given in Eq. 2.5 (p. 83). The solution for $N = 3$ is provided in Appendix D.1 (p. 137).

Once the matrix has been diagonalized, one may compute powers of that matrix as powers of the eigenvalues. This results in the general solution given by

$$\begin{bmatrix} x_n \\ y_n \end{bmatrix} = 1j^n \mathbf{A}^n \begin{bmatrix} 1 \\ 0 \end{bmatrix} = 1j^n \mathbf{E} \Lambda^n \mathbf{E}^{-1} \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

The eigenvalue matrix D is diagonal with the eigenvalues sorted, largest first. The Matlab command `[E,D]=eig(A)` is helpful to find D and E given any A . As we saw above,

$$\Lambda = 1j \begin{bmatrix} 1 + \sqrt{2} & 0 \\ 0 & 1 - \sqrt{2} \end{bmatrix} \approx \begin{bmatrix} 2.414j & 0 \\ 0 & -0.414j \end{bmatrix}.$$

D.1 Pell equation for N=3

This summarizes the solution of Pell's equation due to the Pythagoreans using matrix recursion, for the case of N=3. The integer solutions are shown in on the right. Note that $x_n/y_n \rightarrow \sqrt{3}$, in agreement with the Euclidean algorithm.¹ It seem likely that β_0 could be absorbed in the starting solution, and then be removed from the generating function, other than as the known factor β_0^n

Case of $N = 3$: $[x_0, y_0]^T = [1, 0]^T$, $\beta_0 = j/\sqrt{2}$; Pell-3: $x_n^2 - 3y_n^2 = 1$; $x_n/y_n \xrightarrow{\infty} \sqrt{3}$

Try other trivial solutions such as $[-1, 0]^T$ and $[\pm j, 0]^T$. Perhaps this can provide a clue to the proper value of β_0 .

¹The matlab program for generating this solution is `PellSol3.m`.

$$\begin{array}{l}
\begin{bmatrix} x_1 \\ y_1 \end{bmatrix} = \beta_0 \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \beta_0 \begin{bmatrix} 1 & 3 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} & (1\beta_0)^2 - 3(1\beta_0)^2 = 1 \\
\begin{bmatrix} x_2 \\ y_2 \end{bmatrix} = \beta_0^2 \begin{bmatrix} 4 \\ 2 \end{bmatrix} = \beta_0^2 \begin{bmatrix} 1 & 3 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} & (4\beta_0^2)^2 - 3(2\beta_0^2)^2 = 1 \\
\begin{bmatrix} x_3 \\ y_3 \end{bmatrix} = \beta_0^3 \begin{bmatrix} 10 \\ 6 \end{bmatrix} = \beta_0^3 \begin{bmatrix} 1 & 3 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 4 \\ 2 \end{bmatrix} & (10\beta_0^3)^2 - 3(6\beta_0^3)^2 = 1 \\
\begin{bmatrix} x_4 \\ y_4 \end{bmatrix} = \beta_0^4 \begin{bmatrix} 28 \\ 16 \end{bmatrix} = \beta_0^4 \begin{bmatrix} 1 & 3 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 10 \\ 6 \end{bmatrix} & (28\beta_0^4)^2 - 3(16\beta_0^4)^2 = 1 \\
\begin{bmatrix} x_5 \\ y_5 \end{bmatrix} = \beta_0^5 \begin{bmatrix} 76 \\ 44 \end{bmatrix} = \beta_0^5 \begin{bmatrix} 1 & 3 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 28 \\ 16 \end{bmatrix} & (76\beta_0^5)^2 - 3(44\beta_0^5)^2 = 1
\end{array}$$

List of Figures

1	There is a natural symbiotic relationship between Physics, Mathematics and Engineering, as depicted by this Venn diagram. Physics explores the boundaries. Mathematics provides the method and rigor. engineering transforms the method into technology. While these three disciplines work well together, there is poor communication due to a different vocabulary.	10
2	Table of contents of <i>Stillwell (2002)</i>	11
1.1	Depiction of the argument of Galileo (unpublished book of 1638) as to why weights of different masses (weight) must fall with identical velocity. By joining them with an elastic cord they become one. Thus if the velocity were proportional to the mass, the joined masses would fall even faster. This results in a logical fallacy. This may have been the first time that the principle of conservation of energy was clearly stated.	14
1.2	Mathematical time-line between 1500 BCE and 1650 CE.	16
1.3	Above: Jakob (1655-1705) and Johann (1667-1748) Bernoulli; Below: Leonhard Euler (1707) and Jean le Rond d’Alembert (1717-1783). The figure numbers are from <i>Stillwell (2010)</i>	18
1.4	Time-line of the four centuries from the 16 th and 20 th CE	20
1.5	Sieve of Eratosthenes for the case of $N = 50$	31
1.6	The Euclidean algorithm for finding the GCD of two numbers is one of the oldest algorithms in mathematics, and is highly relevant today. It is both powerful and simple. It was used by the Chinese during the Han dynasty (<i>Stillwell, 2010, p. 70</i>) for reducing fractions. It may be used to find pairs of integers that are coprime (their gcd must be 1), and it may be used to identify factors of polynomials by long division. It has an important sister algorithm called the continued fraction algorithm (CFA), that is so similar in concept that Gauss referred to the Euclidean algorithm as the “continued fraction algorithm” (<i>Stillwell, 2010, p. 48</i>).	34
1.7	The expansion of π to various orders using the CFA, along with the order of the error of each rational approximation. For example $22/7$ has an absolute error ($ 22/7 - \pi $) of about 0.13%.	35
1.8	Beads on a string form perfect right triangles when number of beads on each side satisfy Eq. 1.1.	37
1.9	“Plimpton-322” is a stone tablet from 1800 BCE, displaying a and c values of the Pythagorean triplets $[a, b, c]$. Numbers $(a, c \in \mathbb{N})$, with the property $b = \sqrt{c^2 - a^2} \in \mathbb{N}$, known as Pythagorean triplets, were found carved on a stone tablet from the 19 th century [BCE]. Several of the c values are primes, but not the a values. The stone is item 322 (item 3 from 1922) from the collection of George A. Plimpton. – <i>Stillwell (2010, Exercise 1.2)</i>	38
1.10	This summarizes the solution of Pell’s equation for $N = 2$ using a slightly modified matrix recursion. Note that $x_n/y_n \rightarrow \sqrt{2}$ as $n \rightarrow \infty$, which was what the Pythagoreans were pursuing.	39
1.11	This is a single LC segment of the transmission line show in Fig. 2.2. It may be modeled by the ABCD model as the product of two matrices, as show below. A more detailed analysis shows that the wave number is $\kappa = \sqrt{ZY} = \sqrt{sL \cdot sC} = s\sqrt{LC}$. It follows that the wave velocity is $c = 1/\sqrt{LC}$. The characteristic resistance is $r_c = \sqrt{Z/Y} = \sqrt{sL/sC} = \sqrt{L/C}$	53

1.12 The left panel shows how the real line may be composed with the circle. Each real x value maps to a corresponding point x' on the unit circle. The point $x \rightarrow \infty$ then naturally maps to the north pole N . This simple idea may be extended with the composition of the complex plane with the unit sphere, thus mapping the plane onto the sphere. As with the circle, the point on the complex plane $z \rightarrow \infty$ maps onto the north pole N . This construction is important because while the plane is open (does not include $z \rightarrow \infty$), the sphere is analytic at the north pole. Thus the sphere defines the closed extended plane. Figure from Stillwell (2010, pp. 299-300). 55

1.13 On the left is a color map showing the definition of the complex s plane, with hue (darkness) indicating magnitude and color indicating angle. On the left $w(s) = s$, $u = \sigma$ and $v = v$. On the right $w(s) = s - 1$, a simple shift of one unit in σ is shown. Specifically $u = \sigma - 1$ and $v = \omega$. The color gives the phase of w and hue (color saturation) the magnitude $|w|$, as discussed in the text. 56

1.14 On the left is the function $w(s) = e^s$ and on the right is $s = \log(w)$ 57

1.15 von Helmholtz portrait taken from the English translation of his 1858 paper “On integrals of the hydrodynamic equations that correspond to Vortex motions” (in German) (von Helmholtz, 1978). 70

2.1 The Euclidean Algorithm recursively subtracts n from m until the remainder $m - kn$ is either less than n or zero. For the case depicted here the value of k that renders the remainder less than n is $k = 6$. If one more step were taken ($k = 7$) the remainder becomes negative. By linear interpolation we can find that $m - an = 0$ when $a = m/n$, which for this example is close to $a=6.5$. In this example $6 = \text{floor}(m/n) < n$. 78

2.2 This transmission line (TL) is known as a low-pass filter wave-filter (Campbell, 1922), composed of series inductors having an impedance $Z_k = sL$ and shunt admittance $Y_k = sC$. The characteristic resistance of the TL is $r_0 = \sqrt{Z_k/Y_k}$ and the wave velocity is $\kappa = \sqrt{Z_k Y_k} = s/\sqrt{LC} = s/c$. Thus the wave velocity is $c = 1/\sqrt{LC}$. The length Δ [m] defines the physical size of each cell. For long wavelengths the wave-filter acts as a pure delay. But when the frequency increases above a cutoff frequency $f_c > c/\Delta$, the wavelength $\lambda = c/f$ is less than the size of a section Δ , and the system response becomes very high-order low-pass filter. 80

2.3 Derivation of Euclid’s formula for the Pythagorean triplets $[a, b, c]$, based on a composition of a line, having a rational slope $t = p/q \in \mathbb{Q}$, and a circle $c^2 = a^2 + b^2, [a, b, c] \in \mathbb{N}$. This analysis is attributed to Diophantus (250 CE), and today such equations are called Di-o-phan’tine equations. PTs have applications in architecture and scheduling, and many other practical problems. 81

2.4 Properties of the Fibonacci numbers (Stillwell, 2010, p. 28). 84

3.1 **Move to text** The Schwartz inequality is related to the shortest distance (length of a line) between the ends of the two vectors. $\|U\| = \sqrt{U \cdot U}$ as the dot product of that vector with itself. This theory is widely used in quantum mechanics (Hilbert inner product spaces). 90

3.2 The Schwartz inequality is related to the shortest distance (length of a line) between the ends of the two vectors. $\|U\| = \sqrt{U \cdot U}$ as the dot product of that vector with itself. 91

3.3 Here we see the function $w(z) = \pm\sqrt{z}$ 100

3.4 On the left is the function $w(s) = s^2$ and on the right is $s = \sqrt{w}$ 100

3.5 On the left is the function $w(s) = \tan(z)$ and on the right is its inverse $w(s) = \tan^{-1}(\pi s)$ 101

3.6 On the left is the function $w(s) = s/(1 + s)$, having a zero at $s = 0$ and a pole at $s = -1$. On the right is $w(s) = \sin(\pi s)$. See the discussion in the text for an interpretation of these complex maps. 101

3.7 A schematic representation of a 2-port ABCD electro-mechanic system using Hunt parameters $Z_e(s)$, $z_m(s)$, and $T(s)$: electrical impedance, mechanical impedances, and transduction coefficient (Hunt, 1952; Kim and Allen, 2013). Also $V(f)$, $I(f)$, $F(f)$, and $U(f)$ are the frequency domain voltage, current, force, and velocity respectively. Notice how the matrix method ‘factors’ the 2-port model into three 2×2 matrices. This allows one to separate the physical modeling from the algebra. It is a standard impedance convention that the flows $I(f), U(f)$ are always defined into the port. Thus it is necessary to apply a negative sign on the velocity $-U(f)$ so that it has an outward flow, to feed the next cell with an inward flow. **Replace Φ with V** 103

4.1 The zeta function arguably the most important of the special functions of analysis because it connects the primes to analytic function theory in a fundamental way. 116

4.2 $\angle\zeta(z)$: **Red** $\Rightarrow \angle\zeta(z) < \pm\pi/2$ 116

4.3 Example of a signal flow diagram for the composition of signals $z = g \circ f(x)$ with $y = f(x)$ and $z = g(y)$. 116
